## NOTICE

The Society of Cable Telecommunications Engineers (SCTE) Standards and Operational Practices (hereafter called “documents”) are intended to serve the public interest by providing specifications, test methods and procedures that promote uniformity of product, interoperability, interchangeability, best practices, and the long term reliability of broadband communications facilities. These documents shall not in any way preclude any member or non-member of SCTE from manufacturing or selling products not conforming to such documents, nor shall the existence of such standards preclude their voluntary use by those other than SCTE members.

SCTE assumes no obligations or liability whatsoever to any party who may adopt the documents. Such adopting party assumes all risks associated with adoption of these documents and accepts full responsibility for any damage and/or claims arising from the adoption of such documents.

NOTE: The user’s attention is called to the possibility that compliance with this document may require the use of an invention covered by patent rights. By publication of this document, no position is taken with respect to the validity of any such claim(s) or of any patent rights in connection therewith. If a patent holder has filed a statement of willingness to grant a license under these rights on reasonable and nondiscriminatory terms and conditions to applicants desiring to obtain such a license, then details may be obtained from the standards developer. SCTE shall not be responsible for identifying patents for which a license may be required or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention.

Patent holders who believe that they hold patents which are essential to the implementation of this document have been requested to provide information about those patents and any related licensing terms and conditions. Any such declarations made before or after publication of this document are available on the SCTE web site at <https://scte.org>.

# SERVICE INFORMATION DELIVERED OUT-OF-BAND FOR DIGITAL CABLE TELEVISION

## 1 PURPOSE, SCOPE AND ORGANIZATION

### 1.1 Purpose

This document defines a standard for Service Information (SI) delivered out-of-band on cable. This standard is designed to support “navigation devices” on cable. The current specification defines the syntax and semantics for a standard set of tables providing the data necessary for such a device to discover and access digital and analog services offered on cable.

### 1.2 Scope

This specification defines SI tables delivered via an out-of-band path to support service selection and navigation by digital cable set-top boxes and other “digital cable-ready” devices. The SI tables defined in this standard are formatted in accordance with the Program Specific Information (PSI) data structures defined in MPEG-2 Systems [1].

The formal definition of “digital cable-ready” has a scope broader than that of the current standard. The formal definition includes requirements related to navigation and service selection, demodulation and decoding, video format decoding, Emergency Alert handling, and other aspects. The current specification supports, primarily, the navigation and service selection function for services delivered in the clear, as well as those subject to conditional access.

This specification does not address the Electronic Program Guide application itself or any user interface which might deal with the presentation and application of the Service Information.

### 1.3 Digital Cable Ready Device

A digital cable-ready device can take the form of a cable set-top box, a computer, a television, or a convergence of these. Devices such as digital video recorders may also be cable-ready. A digital cable-ready device capable of processing access controlled digital services supports an interface to a conditional access module. As used here, the term “Host” refers to the capability to support an interface to a standard Point-of-Deployment (POD)<sup>1</sup> security module.

SI data delivered out-of-band is transported in accordance with the Extended Channel Interface defined in SCTE 28. To obtain access to a POD Extended Channel Interface, the digital cable-ready device must act as a Host to a POD security module. The Extended Channel

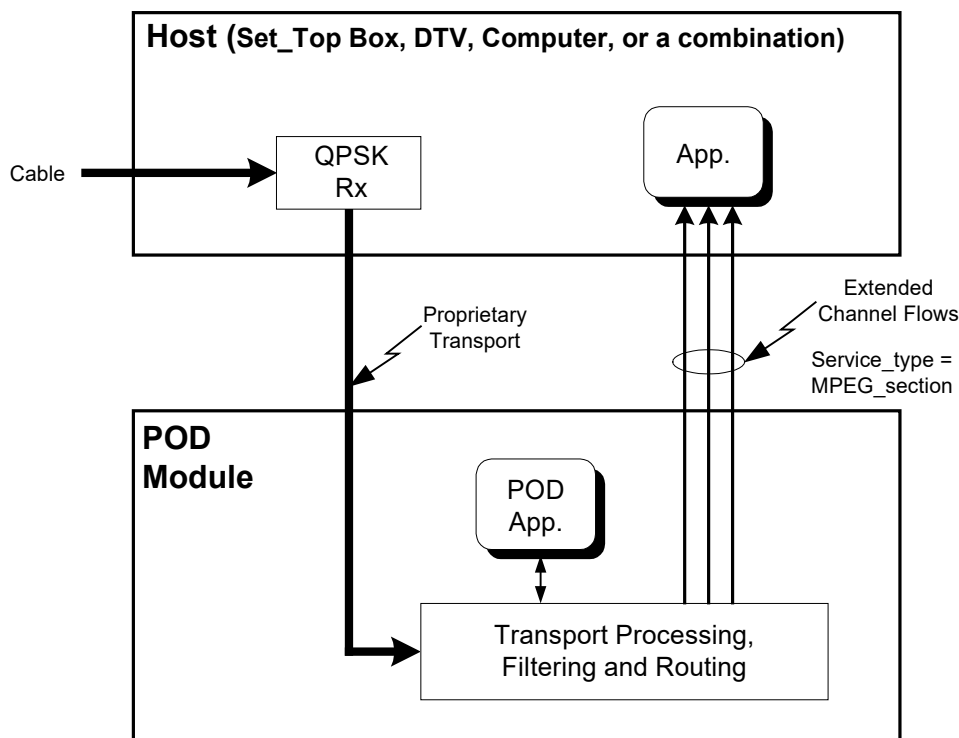

---

<sup>1</sup> The Point-of-Deployment module is also known as a CableCARD™ device.

interface is designed to present the needed SI data to the Host. This data can be used by the Host for channel navigation, construction of electronic program guides and other associated functions.

Figure 1.1 is a high-level block diagram illustrating the POD module to Host interface via the Extended Channel interface. The Host is responsible for providing a standard receiver/QPSK demodulator function for the POD module. The choice of transport format of bits coming across from the receiver/QPSK demodulator to the POD module is by mutual agreement between the POD and the cable head-end equipment. The transport format of data traveling between the Host and POD module on the Extended Channel interface conforms to standards defined in [6].

The POD module may perform various transport, filtering, and error checking/correction functions on the out-of-band data stream as depicted by the box labeled “Transport Processing, Filtering, and Routing.” As described in [6], the Host may request from the POD module to open one or several “flows” in which to receive PSI sections taken from the cable out-of-band data stream. Each flow is associated with a PID value, in accordance with MPEG-2 Transport Stream concepts.

**Figure 1.1 A Framework for the Extended Channel Service Information Stream**

Data flowing to the Host from the POD module that is associated with `Service_type=MPEG_section` is required to be in the form of MPEG PSI data structures. However, data delivered into the POD from cable out-of-band may or may not be organized in a Transport Stream compliant with ISO/IEC 13818-1. In other words, PID values associated with MPEG-2 tables on the Extended Channel interface *may or may not* correspond to MPEG-2 Transport Stream packet header PID values from the cable out-of-band.

Independent of the fact that out-of-band data may reach the POD module via a proprietary method, the data structures delivered across the Extended Channel shall be formatted as MPEG-2 table sections. Like table sections carried in an MPEG-2 Transport Stream, each is associated with a PID value.

#### 1.4 Organization

The sections of this document are organized as follows:

- **Section 1** — Provides this general introduction.
- **Section 2** — Lists applicable documents.
- **Section 3** — Provides a list of acronyms and abbreviations used in this document.
- **Section 4** — Describes the basic structure of sections.
- **Section 5** — Describes formats of sections carried in the Base PID.<sup>2</sup>
- **Section 6** — Explains descriptors applicable to the tables defined in this standard.
- **Section 7** — Describes multilingual character string coding.
- **Annex A** — Defines profiles of choice for cable operator compliance with this standard.
- **Annex B** — Discusses recommendations for receiver implementations.
- **Annex C** — Provides an overview of tables defined in this Service Information standard.
- **Annex D** — Specifies packet rates for delivery of SI data
- **Annex E** — Defines the daylight savings time control fields in the System Time Table.
- **Annex F** — Defines the standard Huffman tables used for text compression.

### 3 DEFINITIONS

#### 3.1 Compliance Notation

As used in this document, “*shall*” denotes a mandatory provision of the standard. “*Should*” denotes a provision that is recommended but not mandatory. “*May*” denotes a feature whose presence does not preclude compliance, that may or may not be present as optional for the implementers.

#### 3.2 Definition of Terms

The following terms are used throughout this document:

***conditional access:*** The control and security of subscriber access to cable or broadcast services and events in the form of video, data and voice communications.

***host:*** A device capable of supporting a POD module by implementing the interface protocol defined in SCTE 28 [6]. SCTE 28 defines the Extended Channel data path through which the SI tables defined in this standard are passed.

***navigation:*** The process of selection and movement among analog and digital services offered on the cable network. The service information tables defined in this protocol assist in the navigation process by providing physical service locations, channel names and numbers for user reference. Those tables supporting electronic program guides also assist the navigation process.

***program element:*** A generic term for one of the elementary streams or other data streams that may be included in a program.

***program:*** A collection of program elements. Program elements may be elementary streams. Program elements need not have any defined time base. Those that do have a common time base are intended for synchronized presentation. The term *program* is also used in the context of a “television program” such as a scheduled daily news broadcast. The distinction between the two usages should be understood by context.

***region:*** as used in this document, a region is a geographical area consisting of one or more countries.

***section* or *table section:*** A data structure comprising a portion of an *ISO/IEC 13818-1*-defined table, such as the Program Association Table (PAT), Conditional Access Table (CAT), or Program Map Table (PMT). The term conforms to MPEG terminology. All sections begin with the `table_ID` and end with the `CRC_32` field. Sections are carried in Transport Stream packets in which the starting point within a packet payload is indicated by the `pointer_field` mechanism defined in the *ISO/IEC 13818-1 Systems* document. The Network Information Table, for example, defines portions of several types of tables.

***service:*** *ISO/IEC 13818-1* uses the term *program* to refer to a collection of program elements with no regard to time. In this Service Information standard, the term *service* is used in this same context to denote a collection of elementary components. Usage of the term *service* clarifies certain discussions that also involve the notion of the term *program* in its traditional meaning — for example, in the statement, “A video service carries a series of programs.” In a broader sense,

*service* is also intended for multimedia services of video, voice and data, as these services become prevalent.

**stream**: An ordered series of bytes. The usual context for the term *stream* involves specification of a particular PID (such as the “Program Map PID stream”), in which case the term indicates a series of bytes extracted from the packet multiplex from packets with the indicated PID value.

### 3.3 Acronyms and Abbreviations

The following acronyms and abbreviations are used within this specification:

<b>AEIT</b>	Aggregate Event Information Table
<b>AETT</b>	Aggregate Extended Text Table
<b>ATSC</b>	Advanced Television Systems Committee
<b>BMP</b>	Basic Multilingual Plane
<b>bslbf</b>	bit serial, leftmost bit first
<b>CAT</b>	Conditional Access Table
<b>CC</b>	Closed Caption
<b>CDS</b>	Carrier Definition Subtable
<b>CRC</b>	Cyclic Redundancy Check
<b>DCM</b>	Defined Channels Map
<b>DTV</b>	Digital Television
<b>ECM</b>	Entitlement Control Message
<b>EMM</b>	Entitlement Management Message
<b>ETSI</b>	European Telecommunications Standards Institute
<b>GPS</b>	Global Positioning System
<b>ICM</b>	Inverse Channel Map
<b>ITU</b>	International Telecommunications Union
<b>L-VCT</b>	Long-form Virtual Channel Table
<b>LSB</b>	Least Significant Bit
<b>MGT</b>	Master Guide Table
<b>MMS</b>	Modulation Mode Subtable
<b>MPEG</b>	Moving Picture Experts Group
<b>MPAA</b>	Motion Picture Association of America
<b>MSB</b>	Most Significant Bit
<b>MSS</b>	Multiple String Structure
<b>MTS</b>	Multi-lingual Text String
<b>NTSC</b>	National Television System Committee
<b>NVOD</b>	Near Video On Demand
<b>OOB</b>	Out-of-band
<b>PAT</b>	Program Association Table
<b>PCR</b>	Program Clock Reference
<b>PES</b>	Packetized Elementary Stream
<b>PID</b>	Packet Identifier
<b>PMT</b>	Program Map Table
<b>POD</b>	Point of Deployment
<b>PSIP</b>	Program and System Information Protocol
<b>PTC</b>	Physical Transmission Channel

<b>PTS</b>	Presentation Time Stamp
<b>rpchof</b>	remainder polynomial coefficients, highest order first
<b>RRT</b>	Rating Region Table
<b>S-VCT</b>	Short-form Virtual Channel Table
<b>SCTE</b>	Society of Cable Telecommunications Engineers
<b>SI</b>	Service Information
<b>SNS</b>	Source Name Subtable
<b>TS</b>	Transport Stream
<b>UTC</b>	Coordinated Universal Time <sup>3</sup>
<b>uimsbf</b>	unsigned integer, most significant bit first
<b>VCM</b>	Virtual Channel Map

### 3.4 Section and Data Structure Syntax Notation

This document contains symbolic references to syntactic elements. These references are typographically distinguished by the use of a different font (e.g., *restricted*), may contain the underscore character (e.g., *sequence\_end\_code*) and may consist of character strings that are not English words (e.g., *dynrng*).

The formats of sections and data structures in this document are described using a C-like notational method employed in *ISO/IEC 13818-1*. Extensions to this method are described in the following sections.

#### 3.4.1 Field Sizes

Each data structure is described in a table format wherein the size in bits of each variable within that section is listed in a column labeled “Bits.” The column adjacent to the Bits column is labeled “Bytes” and indicates the size of the item in bytes. For convenience, several bits within a particular byte or multi-byte variable may be aggregated for the count. An example follows:

**Table 3.1 Field Sizes Example**

	Bits	Bytes	Format
<b>foo_section(){</b>			
<b>section_syntax_indicator</b>	1	1	
...			
<b>if(section_syntax_indicator) {</b>			
<b>table_extension</b>	16	(2)	uimsbf
<b>reserved</b>	2	(1)	bslbf
<b>version_number</b>	5		uimsbf
<b>current_next_indicator</b>	1		bslbf {next, current}
...			
}			
...			

<sup>3</sup> Since unanimous agreement could not be achieved by the ITU on using either the English word order, CUT, or the French word order, TUC, a compromise to use neither was reached.

In the byte count column, items that are conditional (because they are within a loop or conditional statement) are in parentheses. Nested parentheses are used if the loops or conditions are nested.

## 4 TABLE STRUCTURE

This section describes details of the structure of MPEG-2 tables defined in this standard.

Tables and table sections defined in this Service Information standard are structured in the same manner used for carrying *ISO/IEC 13818-1* -defined PSI tables. The MPEG-defined 32-bit CRC is required.

### 4.1 Table ID Ranges and Values

Table 4.1 defines table\_ID ranges and values for tables defined in MPEG and in this standard.

**Table 4.1 Table ID Ranges and Values for Out-of-Band Transport**

Table ID Value (hex)	Tables	PID	Ref.
0x00	<b>ISO/IEC 13818-1 Sections:</b> Program Association Table (PAT)	0	Ref. [1]
0x01	Conditional Access Table (CAT)	1	Ref. [1]
0x02	TS Program Map Table (PMT)	per PAT	Ref. [1]
0x03-0x3F	[ISO Reserved]		
0x40-0x7F	<b>User Private Sections:</b> [User Private for other systems]		
0x80-0xBF	[SCTE User Private]		
0xC0-0xC1	<b>Other Standards:</b> [Used in other standards]		
0xC2	<b>Service Information Tables:</b> Network Information Table (NIT)	0x1FFC	Sec. 5.1
0xC3	Network Text Table (NTT)	0x1FFC	Sec. 5.2
0xC4	Short-form Virtual Channel Table (S-VCT)	0x1FFC	Sec. 5.3
0xC5	System Time Table (STT)	0x1FFC	Sec. 5.4
0xC6	[Used in other standards]	-	-
0xC7	Master Guide Table (MGT)	0x1FFC	Sec. 5.5
0xC8	Reserved	-	-
0xC9	Long-form Virtual Channel Table (L-VCT)	0x1FFC	Sec. 5.6
0xCA	Rating Region Table (RRT)	0x1FFC	Sec. 5.7
0xCB-0xD5	[Used in ATSC]	-	-
0xD6	Aggregate Event Information Table (AEIT)	per MGT	Sec. 5.8
0xD7	Aggregate Extended Text Table (AETT)	per MGT	Sec. 5.9
0xD8	Cable Emergency Alert Message	0x1FFC	Ref. [7]
0xD9-0xFE	[Reserved for future use or by other standards]	-	-

Table sections defined in this Service Information standard, and any created as user extensions to it are considered “private” with respect to *ISO/IEC 13818-1*. Table section types 0x80 through 0xBF are user-defined (outside the scope of this Service Information standard).

The maximum total length of any table section defined in this standard is 1024 bytes, except for the MGT, L-VCT, AEIT and AETT, each of which has a maximum total length of

4096 bytes. This total includes `table_ID`, CRC, and all fields contained within the specific table section.

#### 4.2 Extensibility

This Service Information standard defines a number of tables and table sections. The Service Information standard is designed to be extensible via the following mechanisms:

1. **Reserved Fields:** Fields in this Service Information standard marked `reserved` are reserved for use either when revising this standard, or when another standard is issued that builds upon this one. See Section 4.4 below.
2. **Standard Table Types:** As indicated in Table 4.1, `table_ID` values in the range 0xCE through 0xFE are reserved for use either when revising this Service Information standard, or when another standard is issued that builds upon this one.<sup>4</sup>
3. **User Private Table Types:** As indicated in Table 4.1, `table_id` values in the range 0x80 through 0xBF are reserved for “user private” use. The format of user private tables carried in the Network PID shall conform to the syntax described in Table 4.2.
4. **User Private Descriptors:** Privately defined descriptors may be placed at designated locations throughout the table sections described in this Service Information standard. Ownership of one or more user private descriptors is indicated by the presence of an MPEG `registration_descriptor()` preceding the descriptor(s).

**Table 4.2 Network private table section format**

	Bits	Bytes	Format
<code>network_private_table section(){</code>			
<b>private_table_ID</b>	8	1	uimsbf (0x80 <= table_ID <= 0xBF)
<b>section_syntax_indicator</b>	1	2	Bslbf
<b>zero</b>	1		Bslbf
<b>reserved</b>	2		Bslbf
<b>section_length</b>	12		Uimsbf
if (section_syntax_indicator==1) {			
<b>table_extension</b>	16	(2)	Uimsbf
<b>reserved</b>	2	(1)	Bslbf
<b>version_number</b>	5		Uimsbf
<b>current_next_indicator</b>	1		bslbf {next, current}
<b>section_number</b>	8	(1)	Uimsbf
<b>last_section_number</b>	8	(1)	Uimsbf
}			
<b>zero</b>	3	1	Bslbf
<b>protocol_version</b>	5		see Section 4.4.1
<b>format_identifier</b>	32	4	Uimsbf
<b>private_message_body()</b>	N*8	N	
<b>CRC_32</b>	32	4	Rpchof
<code>}</code>			

<sup>4</sup> Note: Assignment of `table_ID` values in the 0xCE to 0xFE range requires coordination between ATSC and SCTE.

### 4.3 *Reserved Fields*

**reserved** — Fields in this Service Information standard marked “reserved” shall not be assigned by the user, but shall be available for future use. Hosts are expected to disregard reserved fields for which no definition exists that is known to that unit. Fields marked “reserved” shall be set to “1” until such time as they are defined and supported.

**zero** — Indicates the bit or bit field shall be “0”.

### 4.4 *Private Table Section Syntax*

Table 4.2 defines the syntax for user private table sections. The MPEG-defined CRC is required. Refer to *ISO/IEC 13818-1* for definition of MPEG-standard fields.

**private\_table\_ID** — The value of `table_ID` in private table sections shall be in the range 0x80 through 0xBF.

#### 4.4.1 **Protocol Version**

**protocol\_version** — A 5-bit unsigned integer field whose function is to allow, in the future, any defined table type to carry parameters that may be structured fundamentally differently from those defined in the current protocol. At present, all defined table section types in this protocol are defined for `protocol_version` zero only. Nonzero values of `protocol_version` may only be processed by Receivers designed to accommodate the later versions as they become standardized.

#### 4.4.2 **Format Identifier**

**format\_identifier** — A 32-bit unsigned integer value which unambiguously identifies the entity defining this `network_private_table_section()` syntax. Values for `format_identifiers` shall be obtained from SCTE.

#### 4.4.3 **Private Message Body**

**private\_message\_body()** — A data structure defined by the private entity identified by `format_identifier`.

#### 4.4.4 **CRC**

**CRC<sub>32</sub>** — The 32-bit CRC value defined in [1] for PSI sections. The MPEG-2 CRC shall be checked in the POD, and only messages that pass the CRC check shall be forwarded to the Host. The Host shall not check the CRC.

## 5 TABLE SECTION FORMATS

The following sections define the formats of table sections as they are delivered across an Extended Channel Interface.

### 5.1 *Network Information Table*

Sections of the Network Information Table shall be associated on the POD-Host interface with PID value 0x1FFC, the `SI_base` PID. This table delivers sections of non-textual tables applicable system-wide. The table types included are the Carrier Definition Subtable (CDS) and the Modulation Mode Subtable (MMS).

Table 5.1 shows the format of the Network Information Table section.

**table\_ID** — The `table_ID` of the Network Information Table section shall be 0xC2.

**first\_index** — An 8-bit unsigned integer number in the range one to 255 that indicates the index of the first record to be defined in this table section. If more than one record is provided, the additional records define successive table entries following `first_index`. The value zero is illegal and shall not be specified.

**number\_of\_records** — An 8-bit unsigned integer number that specifies the number of records being defined in this table section. The maximum is limited by the maximum allowed length of the table section.

**transmission\_medium** — This 4-bit field shall be set to zero (0x0).

**Table 5.1 Network Information Table section format**

	Bits	Bytes	Format
<b>network_info_table_section(){</b>			
<b>table_ID</b>	8	1	uimsbf value 0xC2
<b>zero</b>	2	2	Bslbf
<b>reserved</b>	2		Bslbf
<b>section_length</b>	12		Uimsbf
<b>zero</b>	3	1	Bslbf
<b>protocol_version</b>	5		Sec. 4.4.1
<b>first_index</b>	8	1	uimsbf range 1-255
<b>number_of_records</b>	8	1	Uimsbf
<b>transmission_medium</b>	4	1	uimsbf
<b>table_subtype</b>	4		uimsbf see Table 5.2
for (i=0; i<number_of_records; i++) {			
if (table_subtype==CDS) {			
<b>CDS_record()</b>		((5))	
}			
if (table_subtype==MMS) {			
<b>MMS_record()</b>		((6))	
}			
<b>descriptors_count</b>	8	(1)	uimsbf range 0-255
for (i=0; i<descriptors_count; i++) {			
<b>descriptor()</b>	*	((*))	optional
}			
}			
for (i=0; i<N; i++) {			
<b>descriptor()</b>	*	(*)	optional
}			
<b>CRC_32</b>	32	4	rpchof
<b>}</b>			

**table\_subtype** — A 4-bit value that defines the type of table delivered in the table section. One instance of a Network Information Table section can define entries within at most one type of table. The **table\_subtype** parameter is defined in Table 5.2.

**Table 5.2 Network Information Table Subtype**

<b>table_subtype</b>	<b>meaning</b>
0	invalid
1	<b>CDS</b> — Carrier Definition Subtable
2	<b>MMS</b> — Modulation Mode Subtable
3-15	Reserved

The receiver shall discard a Network Information Table section with **table\_subtype** indicating an unknown or unsupported **table\_subtype**.

**5.1.1 Carrier Definition Subtable (CDS)**

Table 5.3 defines the structure of the **CDS\_record()**. Each CDS defines a set of carrier frequencies. A full frequency plan table shall be constructed from one or more **CDS\_record()** structures, each defining a starting frequency, a number of carriers, and a frequency spacing for carriers in this group.

The specified carrier represents the nominal center of the spectral band for all modulation methods, including analog. Carrier frequencies in the table thus represent the data carrier frequency for digital transmissions modulated using QAM or PSK.<sup>5</sup>

Each CDS\_record represents a definition of N carriers. The first\_index parameter reflects the index in a flat space between 1 and 255, representing the first carrier in the CDS\_record. Starting from the first CDS\_record defining carriers C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, ..., C<sub>N</sub>, where N = number\_of\_carriers, the carrier index for C<sub>1</sub> is equal to first\_index + I - 1. If the table section includes more than one CDS\_record(), the carrier index of the second CDS\_record would be first\_index plus the number of carriers defined in the first CDS\_record(), namely, first\_index + number\_of\_carriers. References to the Carrier Definition Subtable, such as the CDS\_reference in the virtual\_channel() of Table 5.17, are to the carrier index (a carrier defined within a CDS\_record()), between 1 and N, where N is normally much smaller than 255. These references are *not* to the index of a CDS\_record() itself, which is sequenced from first\_index and is not reset to 1 until it exceeds 255.

Note that the carriers, as defined by one or more CDS\_record(s), may or may not end up sorted in the order of increasing carrier frequency. Certain frequency plans may be specified by overlapping two or more CDS\_record(s), each of which defines equally-spaced carriers.

Note also that carriers may be defined that are currently not in use. To facilitate the compressed delivery format, defined carriers may not reflect reality. An example: carriers at 1, 2, 4, 5, 7, 8 MHz could be defined as eight carriers at 1MHz spacing (3 MHz and 6 MHz do not really exist, or are not currently in use).

**Table 5.3 CDS record format**

	Bits	Bytes	Format
CDS_record(){			
number_of_carriers	8	1	uimsbf
spacing_unit	1	2	bslbf see Table 5.4
zero	1		bslbf
frequency_spacing	14		uimsbf range 1-16,383 units of 10 or 125kHz
frequency_unit	1	2	bslbf see Table 5.5
first_carrier_frequency	15		uimsbf range 0-32,767 units of 10 or 125kHz
}			

**number\_of\_carriers** — An unsigned integer in the range 1 to 255 that represents the number of carriers whose frequency is being defined by this CDS\_record().

**spacing\_unit** — A 1-bit field identifying the units for the frequency\_spacing field. Table 5.4 defines the coding for spacing\_unit.

<sup>5</sup> Note that transmission systems using VSB modulation transmit spectra are not symmetrical about the carrier or pilot tone. Acquisition of a VSB-modulated signal involves computation of the pilot tone (or in analog VSB, the picture carrier) location relative to the center of the band. For example, for the ATSC Digital Television Standard (Ref. [3]), where the channel bandwidth is 6 MHz, the pilot tone is located 310 kHz above the lower edge of the channel, or 2.690 MHz below the specified center of the band. Similarly, for analog NTSC, the picture carrier is 1.25 MHz above the lower edge of the channel, or 1.75 MHz below the specified center of the band.

**Table 5.4 Spacing Unit**

spacing_unit	meaning
0	10 kHz spacing
1	125 kHz spacing

**frequency\_spacing** — A 14-bit unsigned integer number in the range one to 16,383 that defines the frequency spacing in units of either 10 kHz or 125 kHz, depending upon the value of the spacing\_unit parameter. If spacing\_unit is zero, indicating 10 kHz, then a value of one indicates 10 kHz spacing; two indicates 20 kHz, and so on. If the number\_of\_carriers field is one, the frequency\_spacing field is ignored. The maximum frequency spacing that can be represented is  $(2^{14} - 1) * 125 \text{ kHz} = 2047.875 \text{ MHz}$ . The minimum frequency spacing is 10 kHz.

**frequency\_unit** — A 1-bit field identifying the units for the first\_carrier\_frequency field. Table 5.5 defines the coding for frequency\_unit.

**Table 5.5 Frequency Unit**

Frequency_unit	meaning
0	10 kHz units
1	125 kHz units

**first\_carrier\_frequency** — A 15-bit unsigned integer number in the range 0 to 32,767 that defines the starting carrier frequency for the carriers defined in this group, in units of either 10 kHz or 125 kHz, depending on the value of frequency\_unit. If only one carrier is defined for the group, the first\_carrier\_frequency represents its frequency. When the frequency\_unit indicates 125 kHz, the first\_carrier\_frequency can be interpreted as a fractional frequency (1/8 MHz) in the least-significant 3 bits, and an integer number of megahertz in the upper 12 bits. The range of frequencies that can be represented is 0 to  $(2^{15} - 1) * 125 \text{ kHz} = 4095.875 \text{ MHz}$ .

### 5.1.2 Modulation Mode Subtable (MMS)

Table 5.6 defines the structure of the MMS\_record().

**Table 5.6 MMS record format**

	Bits	Bytes	Format
<b>MMS_record(){</b>			
<b>transmission_system</b>	4	1	uimsbf see Table 5.7
<b>inner_coding_mode</b>	4		uimsbf see Table 5.8
<b>split_bitstream_mode</b>	1	1	bslbf {no, yes}
<b>zero</b>	2		bslbf
<b>modulation_format</b>	5		uimsbf see Table 5.9
<b>zero</b>	4	4	bslbf
<b>symbol_rate</b>	28		uimsbf units: symbols per sec.
<b>}</b>			

**transmission\_system** — A 4-bit field that identifies the transmission standard employed for the waveform defined by this MMS record. Table 5.7 defines the coding for transmission\_system.

**Table 5.7 Transmission System**

<b>transmission_system</b>	<b>meaning</b>
0	<b>unknown</b> — The transmission system is not known.
1	Reserved (ETSI)
2	<b>ITU-T annex B</b> — The transmission system conforms to the ITU North American standard specified in Annex B of ITU Rec. J.83 [10].
3	Defined for use in other systems
4	<b>ATSC</b> — The transmission system conforms to the ATSC Digital Television Standard [3].
5-15	Reserved (satellite)

**inner\_coding\_mode** — A 4-bit field that indicates the coding mode for the inner code associated with the waveform described in this MMS record. The following values are currently defined: 5/11, 1/2, 3/5, 2/3, 3/4, 4/5, 5/6, and 7/8. Coding of the `inner_coding_mode` field is shown in Table 5.8.

**modulation\_format** — A 5-bit field that defines the basic modulation format for the carrier. Table 5.9 defines the parameter.

**Table 5.8 Inner Coding Mode**

<b>inner_coding_mode</b>	<b>meaning</b>
0	rate 5/11 coding
1	rate 1/2 coding
2	Reserved
3	rate 3/5 coding
4	Reserved
5	rate 2/3 coding
6	Reserved
7	rate 3/4 coding
8	rate 4/5 coding
9	rate 5/6 coding
10	Reserved
11	rate 7/8 coding
12-14	Reserved
15	none — indicates that the waveform does not use concatenated coding

**Table 5.9 Modulation Format**

<b>modulation_format</b>	<b>meaning</b>
0	<b>unknown</b> — The modulation format is unknown.
1	<b>QPSK</b> — The modulation format is QPSK (Quadrature Phase Shift Keying).
2	<b>BPSK</b> — The modulation format is BPSK (Binary Phase Shift Keying).
3	<b>OQPSK</b> — The modulation format is offset QPSK.
4	<b>VS8</b> — The modulation format is 8-level VSB (Vestigial Sideband).
5	<b>VS16</b> — The modulation format is 16-level VSB.
6	<b>QAM 16</b> — Modulation format 16-level Quadrature Amplitude Modulation (QAM).
7	<b>QAM 32</b> — 32-level QAM
8	<b>QAM 64</b> — 64-level QAM
9	<b>QAM 80</b> — 80-level QAM
10	<b>QAM 96</b> — 96-level QAM
11	<b>QAM 112</b> — 112-level QAM
12	<b>QAM 128</b> — 128-level QAM
13	<b>QAM 160</b> — 160-level QAM
14	<b>QAM 192</b> — 192-level QAM
15	<b>QAM 224</b> — 224-level QAM
16	<b>QAM 256</b> — 256-level QAM
17	<b>QAM 320</b> — 320-level QAM
18	<b>QAM 384</b> — 384-level QAM
19	<b>QAM 448</b> — 448-level QAM
20	<b>QAM 512</b> — 512-level QAM
21	<b>QAM 640</b> — 640-level QAM
22	<b>QAM 768</b> — 768-level QAM
23	<b>QAM 896</b> — 896-level QAM
24	<b>QAM 1024</b> — 1024-level QAM
25-31	Reserved

**symbol\_rate** — A 28-bit unsigned integer field that indicates the symbol rate in symbols per second associated with the waveform described in this MMS record.

### 5.1.3 Descriptors Count

**descriptors\_count** — An 8-bit unsigned integer value in the range 0 to 255 representing the number of descriptor blocks to follow.

**descriptor()** — The table section may include at its end one or more structures of the form tag, length, data. The number of descriptors present is determined indirectly by processing the **section\_length** field. Descriptors are defined in Section 6.

## 5.2 Network Text Table

Sections of the Network Text Table shall be associated on an Extended Channel Interface with PID value 0x1FFC, the **SI\_base** PID. This table delivers sections of textual tables applicable system-wide. Each instance of Network Text Table is associated with a language, as such the textual information may be provided multi-lingually. The Network Text Table delivers the Source Name Subtable (SNS).

Table 5.10 shows the format of the Network Text Table.

The Network Text Table carries Multilingual Text Strings, formatted as defined in Section 7.2. Text strings included in the Network Text Table shall not include format effectors (defined in Section 7.1.2). If format effectors are present in a text block, the Host is expected to disregard them.

**Table 5.10 Network Text Table section format**

	Bits	Bytes	Format
<b>network_text_table_section(){</b>			
<b>table_ID</b>	8	1	uimsbf value 0xC3
<b>zero</b>	2	2	bslbf
<b>reserved</b>	2		bslbf
<b>section_length</b>	12		uimsbf
<b>zero</b>	3	1	
<b>protocol_version</b>	5		see Sec. 4.4.1
<b>ISO_639_language_code</b>	24	3	per ISO 639.2/B
<b>transmission_medium</b>	4	1	uimsbf
<b>table_subtype</b>	4		uimsbf see Table 5.11
if (table_subtype==SNS) {			
<b>source_name_subtable()</b>	*	(*)	
}			
for (i=0; i<N; i++) {			
<b>descriptor()</b>	*	(*)	optional
}			
<b>CRC_32</b>	32	4	rpchof
<b>}</b>			

**table\_ID** — The table\_ID of the Network Text Table section shall be 0xC3.

**ISO\_639\_language\_code** — A 3-byte language code per ISO 639.2/B defining the language associated with the text carried in this Network Text Table. The ISO\_639\_language\_code field contains a three-character code as specified by ISO 639.2/B. Each character is coded into 8 bits according to ISO 8859-1 (ISO Latin-1) and inserted, in order, into the 24-bit field. The value 0xFFFFFFFF shall be used in case the text is available in one language only. The value 0xFFFFFFFF shall represent a “wild card” match when filtering by language.

**transmission\_medium** — This 4-bit field shall be set to zero (0x0).

**table\_subtype** — A 4-bit value that defines the type of table delivered in the table section. One instance of a Network Text Table section can define entries within at most one type of table. The table\_subtype parameter is defined in Table 5.11.

**Table 5.11 Network Text Table Subtype**

table_subtype	meaning
0	invalid
1-5	Reserved
6	<b>SNS</b> — Source Name Subtable
7-15	Reserved

A Host shall discard a Network Text Table section with table\_subtype indicating an unknown or unsupported value.

The SNS can provide a textual name associated with each service defined in the Short-form Virtual Channel Table, by reference to its `source_ID`. The format of the `source_name__subtable()` is given in Table 5.12.

**number\_of\_SNS\_records** — An unsigned 8-bit integer number in the range 1 to 255 that specifies the number of records being defined in this table section.

**application\_type** — A Boolean flag, when set, indicates that the name string being defined is for an application of the given `application_ID`. When the flag is clear, the name string being defined is for a source of the given `source_ID`. Support for application-type virtual channels is optional. Hosts not supporting application-type virtual channels may disregard name strings associated with these VC. Support for application-type virtual channels is beyond the scope of this standard.

**application\_ID** — A 16-bit unsigned integer value identifying the application associated with the name string that follows. This field may be disregarded by Hosts not supporting application-type virtual channels.

**source\_ID** — A 16-bit unsigned integer value identifying the programming source associated with the source name to follow.

**name\_length** — An unsigned 8-bit integer number in the range 1 to 255 that defines the number of bytes in the `source_name()` that follows.

**source\_name()** — A Multilingual Text String defining the name of the source or application, formatted according to the rules defined in Section 7.1.

**Table 5.12 Source Name Subtable format**

	Bits	Bytes	Format
<b>source_name_subtable(){</b>			
<b>number_of_SNS_records</b>	8	1	uimsbf range 1-255
for (i=0; i<number_of_SNS_records; i++) {			
<b>application_type</b>	1	(1)	bslbf {false, true}
<b>zero</b>	7		bslbf
if (application_type) {			
<b>application_ID</b>	16	((2))	uimsbf
} else {			
<b>source_ID</b>	16	((2))	uimsbf
}			
<b>name_length</b>	8	(1)	size of source_name() (L)
<b>source_name()</b>	L*8	(L)	multilingual text
<b>SNS_descriptors_count</b>	8	(1)	uimsbf range 0-255
for (i=0; i<SNS_descriptors_count; i++) {			
<b>descriptor()</b>	*	((*))	
}			
}			
}			

**SNS\_descriptors\_count** — An unsigned 8-bit integer number, in the range 0 to 255, that defines the number of descriptors to follow.

**descriptor()** — The table section may include, at its end, one or more structures of the form tag, length, data. The number of descriptors present is determined indirectly by processing the section\_length field. Descriptors are defined in Section 6.

### 5.3 Short-form Virtual Channel Table Section

The Short-form Virtual Channel Table sections deliver portions of the Virtual Channel Map (VCM), the Defined Channels Map (DCM) and the Inverse Channel Map (ICM). Sections of the Short-form Virtual Channel Table shall be associated on an Extended Channel Interface with PID value 0x1FFC, the SI\_base PID.

Table 5.13 shows the syntax of the Short-form Virtual Channel Table section.

**Table 5.13 Short-form Virtual Channel Table section format**

	Bits	Bytes	Format
<b>shortform_virtual_channel_table_section(){</b>			
<b>table_ID</b>	8	1	uimsbf value 0xC4
<b>zero</b>	2	2	bslbf
<b>reserved</b>	2		bslbf
<b>section_length</b>	12		uimsbf
<b>zero</b>	3	1	bslbf
<b>protocol_version</b>	5		see Sec. 4.4.1
<b>transmission_medium</b>	4	1	uimsbf
<b>table_subtype</b>	4		uimsbf see Table 5.14
<b>VCT_ID</b>	16	2	uimsbf
if (table_subtype==DCM) {			
<b>DCM_structure()</b>	*	(*)	
}			
if (table_subtype== VCM) {			
<b>VCM_structure()</b>	*	(*)	
}			
if (table_subtype== ICM) {			
<b>ICM_structure()</b>	*	(*)	
}			
for (i=0; i<N; i++) {			
<b>descriptor()</b>	*	(*)	optional
}			
<b>CRC_32</b>	32	4	rpchof
<b>}</b>			

**table\_ID** — The table\_ID of the Short-form Virtual Channel Table shall be 0xC4.

**transmission\_medium** — This 4-bit field shall be set to zero (0x0).

**table\_subtype** — A 4-bit field that indicates the map type being delivered in this S-VCT section. Three map types are currently defined, the Virtual Channel Map (VCM), the Defined Channels Map (DCM), and the Inverse Channel Map (ICM). Table 5.14 defines table\_subtype.

**Table 5.14 S-VCT Table Subtypes**

table_subtype	meaning
0	<b>VCM</b> — Virtual Channel Map
1	<b>DCM</b> — Defined Channels Map
2	<b>ICM</b> — Inverse Channel Map
3-15	Reserved

An S-VCT section received with table\_subtype indicating an unknown or unsupported map type shall be discarded.

**vct\_id** — A 16-bit unsigned integer value, in the range 0x0000 to 0xFFFF, indicating the VCT to which the channel definitions in this table section apply. This 16-bit field may be used by the POD module for filtering purposes. Only one version of the S-VCT, corresponding to one value of vct\_id, shall be delivered to the Host across the Extended Channel interface at a given time.

**5.3.1 Defined Channels Map**

Table 5.15 shows the format of the DCM\_structure().

**Table 5.15 DCM structure format**

	Bits	Bytes	Format
<b>DCM_structure(){</b>			
<b>zero</b>	4	2	bslbf
<b>first_virtual_channel</b>	12		uimsbf range 0-4095
<b>zero</b>	1	1	bslbf
<b>DCM_data_length</b>	7		uimsbf range 1-127
for (i=0; i<DCM_data_length; i++) {			
<b>range_defined</b>	1	(1)	bslbf {no, yes}
<b>channels_count</b>	7		uimsbf range 1-127
}			
<b>}</b>			

**first\_virtual\_channel** — An unsigned 12-bit integer reflecting the first virtual channel whose existence is being provided by this table section, for the map identified by the vct\_id field. The range is 0 to 4095.

**DCM\_data\_length** — A 7-bit unsigned integer number, in the range 1 to 127, that defines the number of DCM data fields to follow in the table section.

The DCM data bytes taken as a whole define which virtual channels, starting at the channel number defined by first\_virtual\_channel, are defined and which are not. Each DCM\_data\_field defines two pieces of data: a flag indicating whether this block of channels is defined or not, and the number of channels in the block. The bytes are interpreted in an accumulative way, with a pointer into the Short-form Virtual Channel Table which is initialized to first\_virtual\_channel. As each byte is processed, the pointer is incremented by the number of channels indicated by the channels\_count field.

For example, if channels 2-90, 200-210, 400-410, 600-610, 800-810, and 999 were defined, and first\_virtual\_channel was zero, the DCM data sequence (in decimal) would be the

following, where underlined numbers have the `range_defined` bit set: 2, 89, 109, 11, 127, 62, 11, 127, 62, 11, 127, 62, 11, 127, 61, 1.

**range\_defined** — A Boolean flag that indicates, when true, that the number of channels given by `channels_count` is defined in the VCT, starting at the current pointer value. When the flag is clear, the number of channels equal to `channels_count` are currently not defined starting at the current pointer value.

**channels\_count** — An unsigned 7-bit integer number, in the range one to 127, that indicates the number of defined (or undefined) channels in a group.

### 5.3.2 Virtual Channel Map

Table 5.16 shows the format of the `VCM_structure()`.

**Table 5.16 VCM structure format**

	Bits	Bytes	Format
<code>VCM_structure(){</code>			
<b>zero</b>	2	1	bslbf
<b>descriptors_included</b>	1		bslbf {no, yes}
<b>zero</b>	5		bslbf
<b>splice</b>	1	1	bslbf {no, yes}
<b>zero</b>	7		bslbf
<b>activation_time</b>	32	4	uimsbf
<b>number_of_VC_records</b>	8	1	
for (i=0; i<number_of_VC_records; i++) {			
<b>virtual_channel()</b>	*	(*)	
}			
}			

**descriptors\_included** — A Boolean flag that indicates, when set, that one or more record-level descriptors are present in the table section. Record-level descriptors are those defined in Table 5.17 following the “if (descriptors\_included)” statement. When the flag is clear, the record-level descriptor block is absent. The `descriptors_included` flag is not applicable to the section level descriptors shown at the bottom of Table 5.13.

The activation time indicates the time at which the data delivered in the table section will be valid.

**splice** — A Boolean flag that indicates, when set, that the Host should arm video processing hardware to execute the application of the data delivered in the `VCM_structure()` at the next MPEG-2 video splice point if the virtual channel changes described in the table section apply to a currently acquired channel, and the `activation_time` is reached. If the activation is immediate or specified as a time that has since passed, the data should be applied immediately. When the `splice` flag is clear, the virtual channel change is made directly, without arming video hardware for a splice.

**activation\_time** — A 32-bit unsigned integer field providing the absolute second the virtual channel data carried in the table section will be valid, defined as the number of seconds since 0000 Hours UTC, January 6<sup>th</sup>, 1980. If the `GPS.UTC_offset` delivered in the System Time Table is zero, `activation_time` includes the correction for leap seconds. Otherwise, `activation_time` can be converted to

UTC by subtracting the `GPS.UTC_offset`. If the `activation_time` is in the past, the data in the table section shall be considered valid immediately. An `activation_time` value of zero shall be used to indicate immediate activation.

A Host may enter a virtual channel record whose activation times are in the future into a queue. Such a queue may be called a *pending virtual channel* queue. Hosts are not required to implement a pending virtual channel queue, and may choose to discard any data that is not currently applicable.

`number_of_VC_records` — An 8-bit unsigned integer number, in the range 1 to 255, that identifies the number of `virtual_channel()` records to follow in the table section. The number of records included is further limited by the allowed maximum table section length.

`virtual_channel()` — Table 5.17 defines the `virtual_channel()` record structure.

**Table 5.17 Virtual channel record format**

	Bits	Bytes	Format
<code>virtual_channel(){</code>			
<b>zero</b>	4	2	bslbf
<b>virtual_channel_number</b>	12		uimsbf range 0-4095
<b>application_virtual_channel</b>	1	1	bslbf {no, yes}
<b>zero</b>	1		bslbf
<b>path_select</b>	1		bslbf see Table 5.18
<b>transport_type</b>	1		bslbf see Table 5.19
<b>channel_type</b>	4		uimsbf see Table 5.20
if(application_virtual_channel) {			
<b>application_ID</b>	16	(2)	
} else {			
<b>source_ID</b>	16	(2)	
}			
if(transport_type==MPEG_2) {			
<b>CDS_reference</b>	8	((1))	uimsbf range 1-255
<b>program_number</b>	16	((2))	
<b>MMS_reference</b>	8	((1))	uimsbf range 1-255
} else { /* non-MPEG-2 */			
<b>CDS_reference</b>	8	((1))	uimsbf range 0-255
<b>scrambled</b>	1	((1))	bslbf {no, yes}
<b>zero</b>	3		bslbf
<b>video_standard</b>	4		uimsbf see Table 5.21
<b>zero</b>	16	((2))	bslbf
}			
if(descriptors_included) {			
<b>descriptors_count</b>	8	(1)	uimsbf
for (i=0; i<descriptors_count; i++) {			
<b>descriptor()</b>	*	((*))	
}			
}			
}			

`virtual_channel_number` — An unsigned 12-bit integer, in the range zero to 4095, reflecting the virtual channel whose definition is being provided by this virtual channel record, for the map identified by the `VCT_ID` field.

**application\_virtual\_channel** — A binary flag that, when set, indicates this virtual channel defines an access point represented by the `application_ID`. When the flag is clear, the channel is not an application access point, and this virtual channel defines an access point represented by the `source_ID`. Support for application-type virtual channels is optional. Hosts not supporting application-type virtual channels may disregard all data associated with them. Support for application-type virtual channels is beyond the scope of this standard.

**path\_select** — A 1-bit field that associates the virtual channel with a transmission path. For the cable transmission medium, `path_select` identifies which physical cable carries the Transport Stream associated with this virtual channel. Table 5.18 defines `path_select`.

**Table 5.18 Path Select**

<code>path_select</code>	meaning
0	path 1
1	path 2

**transport\_type** — A 1-bit field identifying the type of transport carried on this carrier as either being an MPEG-2 transport (value zero), or not (value one). Table 5.19 defines the coding.

**Table 5.19 Transport Type**

<code>transport_type</code>	meaning
0	MPEG-2 transport
1	non-MPEG-2 transport

**channel\_type** — A 4-bit field defining the channel type. Table 5.20 defines `channel_type`.

**Table 5.20 Channel Type**

<code>channel_type</code>	meaning
0	<b>normal</b> — Indicates that the record is a regular virtual channel record. For non-MPEG-2 channels, the <code>waveform_type</code> shall be defined as “normal.”
1	<b>hidden</b> — Indicates that the record identifies a virtual channel that may not be accessed by the user by direct entry of the channel number (hidden). Hidden channels are skipped when the user is channel surfing, and appear as if undefined if accessed by direct channel entry. Programs constructed for use by specific applications (such as NVOD theaters) utilize hidden virtual channels. If a <code>channel_properties_descriptor()</code> is present and the <code>hide_guide</code> bit is 0, the channel may be considered to be <i>inactive</i> . Inactive channels may appear in EPG displays.
2-15	<b>reserved</b> — Hosts are expected to treat virtual channel records of unknown <code>channel_type</code> the same as non-existent (undefined) channels.

**application\_ID** — A 16-bit unsigned integer number, in the range 0x0001 to 0xFFFF, that identifies the application associated with the virtual channel, on a system-wide basis. One particular program guide application, for example, may look for a program carrying data in its native transmission format by searching through the Short-form Virtual Channel Table for a match on its assigned `application_ID`. In some cases, one application may be able to process streams associated with more than one application ID. The application ID may be used to distinguish

content as well as format, for the benefit of processing within the application. The value zero for `application_ID` shall not be assigned; if specified in a Virtual Channel record, the value zero indicates “unknown” or “inapplicable” for the `application_ID/source_ID` field.

Support for application-type virtual channels is optional. Hosts not supporting application-type virtual channels may disregard all data associated with them. Support for application-type virtual channels is beyond the scope of this standard.

**source\_ID** — A 16-bit unsigned integer number, in the range 0x0000 to 0xFFFF, that identifies the programming source associated with the virtual channel, on a system-wide basis. In this context, a *source* is one specific source of video, text, data, or audio programming. For the purposes of referencing virtual channels to the program guide database, each such program source is associated with a unique value of `source_ID`. The `source_ID` itself may appear in an EPG database, where it tags entries to specific services. The value zero for `source_ID`, if used, shall indicate the channel is not associated with a source ID.

**program\_number** — A 16-bit unsigned integer number that associates the virtual channel number being defined with services defined in the Program Association and TS Program Map Table sections. Access to elementary streams defined in each virtual channel record involves first acquiring the Transport Stream on the carrier associated with the virtual channel, then referencing the Program Association section in PID 0 to find the PID associated with the TS Program Map Table section for this `program_number`. PIDs for each elementary stream are then found by acquisition of the TS Program Map Table section.

A `program_number` with value 0x0000 (invalid as a regular program number) is reserved to indicate that the Host is expected to discard the corresponding virtual channel record from the queue of pending virtual channel changes. Records are identified in the pending queue by their `activation_time`, `VCT_ID`, and `virtual_channel_number`. If no pending virtual channel change is found in the Host’s queue, no action should be taken for this virtual channel (i.e. the record is expected to be discarded).

For inactive channels (those not currently present in the Transport Stream), `program_number` shall be set to zero. This number shall **not** be interpreted as pointing to a Program Map Table entry.

**descriptors\_count** — An 8-bit unsigned integer value, in the range 0 to 255, that defines the number of descriptors to follow.

**CDS\_reference** — An unsigned 8-bit integer number, in the range 0 to 255, that identifies the frequency associated with this virtual channel. Values 1 to 255 of `CDS_reference` are used as indices into the Carrier Definition Subtable to find a frequency to tune to acquire the virtual channel. The value zero is reserved to indicate that the referenced service is carried on *all* digital multiplexes in this VCM. The `CDS_reference` field shall be disregarded for inactive channels.

**MMS\_reference** — An 8-bit unsigned integer value, in the range 0 to 255, that references an entry in the Modulation Mode Subtable (MMS). The value zero is illegal and shall not be specified. For digital waveforms, the `MMS_reference` associates the carrier with a digital modulation mode. For Host implementations that support only one set of modulation parameters, in systems in which one modulation method is used for all carriers, storage and processing of the `MMS_reference` is unnecessary. The `MMS_reference` field shall be disregarded for inactive channels.

**video\_standard** — A 4-bit field that indicates the video standard associated with this non-Standard virtual channel. Table 5.21 defines `video_standard`.

**Table 5.21 Video Standard**

<b>video_standard</b>	<b>meaning</b>
0	<b>NTSC</b> — The video standard is NTSC
1	<b>PAL 625</b> — The video standard is 625-line PAL
2	<b>PAL 525</b> — The video standard is 525-line PAL
3	<b>SECAM</b> — The video standard is SECAM
4	<b>MAC</b> — The video standard is MAC
5-15	Reserved

**descriptor()** — The table section may include, at its end, one or more structures of the form `tag, length, data`. The number of descriptors present is determined indirectly by processing the `section_length` field. Descriptors are defined in Section 6.

### 5.3.3 Inverse Channel Map

The Inverse Channel Map, once reconstructed in the Host from a sequence of Virtual Channel records that belong to the ICM, consists of a list of `source_ID/virtual_channel_number` pairs, ordered by `source_ID`. The Host may use this table to quickly find the virtual channel carrying the program given by a particular value of `source_ID` (by binary search), if such a virtual channel exists. One Inverse Channel Map can be defined per Virtual Channel Map. The ICM may be constructed from the VCM, or linear searches may be done to resolve `source_ID` references. Transmission of the ICM is therefore optional.

Virtual channels that provide access points for applications (i.e., with the `application_virtual_channel` flag set to “yes”) are not included in the ICM.

Table 5.22 describes the format of the `ICM_structure()`.

**Table 5.22 ICM structure format**

	<b>Bits</b>	<b>Bytes</b>	<b>Format</b>
<b>ICM_structure(){</b>			
<b>zero</b>	4	2	bslbf
<b>first_map_index</b>	12		uimsbf range 0-4095
<b>zero</b>	1	1	bslbf
<b>record_count</b>	7		uimsbf range 1-127
for (i=0; i<record_count; i++) {			
<b>source_ID</b>	16	(2)	uimsbf
<b>zero</b>	4	(2)	bslbf
<b>virtual_channel_number</b>	12		uimsbf range 0-4095
}			
}			

**first\_map\_index** — A 12-bit unsigned integer, in the range 0 to 4095, that represents the index into the Inverse Channel Map where data carried in this `ICM_structure()` should be stored.

**record\_count** — A 7-bit unsigned integer value, in the range 1 to 127, that represents the total number of `source_ID`/ `virtual_channel` pairs defined in this table section.

**source\_ID** — A 16-bit unsigned integer number, in the range 0x0000 to 0xFFFF, that identifies the source associated with the virtual channel, on a system-wide basis. In this context, a “source” is one specific source of video, text, data, or audio programming. For the purposes of referencing virtual channels to the program guide database, each such source is associated with a unique value of `source_ID`.

**virtual\_channel\_number** — A 12-bit unsigned integer value, in the range 0 to 4095, that represents the virtual channel, in the Short-form Virtual Channel Table section (ref. Table 5.13) given by `VCT_ID`, associated with the given `source_ID` through the `virtual_channel()` record (ref. Table 5.17). A `virtual_channel_number` of zero indicates that the program given by `source_ID` is currently not carried in this Short-form Virtual Channel Table. Such placeholders are useful in the case where the existence of a certain program within a VCM may come and go.

#### 5.4 System Time Table Section

The System Time Table is used to synchronize Hosts with accurate calendar time. The System Time Table shall be associated on an Extended Channel Interface with PID value 0x1FFC, the `SI_base` PID. Rate of transmission is typically once per minute, at second *00* of each minute.

The processing of the System Time Table in the Host is time-critical. Delays between reception and processing of the table section increase the inaccuracy of timed events. Processing delays should be kept below 200 milliseconds.

Table 5.23 shows the format of the System Time Table section.

**Table 5.23 System Time Table section format**

	Bits	Bytes	Format
<code>system_time_table_section(){</code>			
<b>table_ID</b>	8	1	uimbsf value 0xC5
<b>zero</b>	2	2	bslbf
<b>reserved</b>	2		bslbf
<b>section_length</b>	12		uimbsf
<b>zero</b>	3	1	
<b>protocol_version</b>	5		see Sec. 4.4.1
<b>zero</b>	8	1	bslbf
<b>system_time</b>	32	4	uimbsf
<b>GPS_UTC_offset</b>	8	1	uimbsf seconds
for (i=0; i<N; i++) {			
<b>descriptor()</b>	*	(*)	optional
}			
<b>CRC_32</b>	32	4	rpchof
}			

**table\_ID** — The `table_ID` of the System Time Table shall be 0xC5.

**system\_time** — A 32-bit unsigned integer quantity representing the current system time, as the number of GPS seconds since 0000 Hours UTC, January 6th, 1980. The `system_time` value may or

may not include the correction factor for leap seconds, depending upon the value of `GPS.UTC_offset`, as described below.

**GPS.UTC\_offset** — An 8-bit value that serves dual roles. When set to zero, the field indicates that the `system_time` field carries UTC time directly. When `GPS.UTC_offset` is not equal to zero, it is interpreted as an 8-bit unsigned integer that defines the current offset in whole seconds between GPS and UTC time standards. To convert GPS time to UTC, the `GPS.UTC_offset` is subtracted from GPS time. Whenever the International Bureau of Weights and Measures decides that the current offset is too far in error, an additional leap second may be added (or subtracted), and the `GPS.UTC_offset` will reflect the change.

**descriptor()** — The table section may include at its end one or more structures of the form tag, length, data. The number of descriptors present is determined indirectly by processing the `section_length` field. Descriptors are defined in Section 6.

### 5.5 Master Guide Table (MGT)

The Master Guide Table is used to indicate the location, size, and version of tables it references. The MGT shall be associated on an Extended Channel Interface with PID value 0x1FFC, the `SI_base` PID. The MGT syntax is shown in Table 5.24. Syntax and semantics are identical to [5], except that additional table types are added to refer to all tables defined in this protocol.

**table\_ID** — The `table_ID` of the Master Guide Table section shall be 0xC7.

**section\_syntax\_indicator** — This 1-bit field shall be set to ‘1’. It denotes that the section follows the generic section syntax beyond the section length field.

**private\_indicator** — This 1-bit field shall be set to ‘1’.

**section\_length** — 12-bit field specifying the number of remaining bytes in this section immediately following the `section_length` field up to the end of the section. The value of the `section_length` shall be no larger than 4,093.

**map\_ID** — This 16-bit field may be used by the POD module for filtering purposes. The Host is expected to ignore `map_ID`. Only one version of the MGT, corresponding to one value of `map_ID` shall be delivered to the Host across an Extended Channel Interface at a given time. Consequently, the Host may disregard `map_ID` and may process the MGT `version_number` field as an indication that the MGT version has changed.

*Note:* The `map_ID` may be considered to be an identifier for this instance of the Master Guide Table. In some applications, the POD module may receive multiple Master Guide Table sections corresponding to distinct channel maps. In this case, the POD module is responsible for accepting one MGT and discarding the others using information provided by means outside the scope of this standard.

**Table 5.24 Master Guide Table section format**

	Bits	Bytes	Format
<b>master_guide_table_section () {</b>			
<b>table_ID</b>	8	1	0xC7
<b>section_syntax_indicator</b>	1	2	'1'
<b>private_indicator</b>	1		'1'
<b>reserved</b>	2		'11'
<b>section_length</b>	12		uimsbf
<b>map_ID</b>	16	2	uimsbf
<b>reserved</b>	2	1	'11'
<b>version_number</b>	5		uimsbf
<b>current_next_indicator</b>	1		'1'
<b>section_number</b>	8	1	0x00
<b>last_section_number</b>	8	1	0x00
<b>protocol_version</b>	8	1	uimsbf
<b>tables_defined</b>	16	2	uimsbf
for (i=0;i<tables_defined;i++) {			
<b>table_type</b>	16	2	uimsbf
<b>reserved</b>	3	2	'111'
<b>table_type_PID</b>	13		uimsbf
<b>reserved</b>	3	1	'111'
<b>table_type_version_number</b>	5		uimsbf
<b>number_bytes</b>	32	4	uimsbf
<b>reserved</b>	4	2	'1111'
<b>table_type_descriptors_length</b>	12		uimsbf
for (k=0;k<N;k++)			
<b>descriptor()</b>	var		
}			
<b>reserved</b>	4	2	'1111'
<b>descriptors_length</b>	12		uimsbf
for (I = 0;I< N;I++)			
<b>descriptor()</b>	var		
<b>CRC_32</b>	32	4	rpchof
}			

**version\_number** — This 5-bit field is the version number of MGT. The version number shall be incremented by 1 modulo 32 when any field in the `table_types` defined in the loop below or the MGT itself changes.

**current\_next\_indicator** — This 1-bit indicator is always set to '1' for the MGT section; the MGT sent is always currently applicable.

**section\_number** — The value of this 8-bit field shall always be 0x00 (this table is only one section long).

**last\_section\_number** — The value of this 8-bit field shall always be 0x00.

**protocol\_version** — An 8-bit unsigned integer field whose function shall be to allow, in the future, this table type to carry parameters that may be structured differently than those defined in the current protocol. At present, the only valid value for `protocol_version` is zero. Non-zero values of `protocol_version` may only be processed by Hosts designed to accommodate the later versions as they become standardized.

**tables\_defined** — This 16-bit unsigned integer in the range 0 to 65,535 represents the number of tables in the following loop.

**table\_type** — This 16-bit unsigned integer specifies the type of table, based on Table 5.25.

**Table 5.25 MGT Table Types**

<b>table_type</b>	<b>Meaning</b>
0x0000-0x0001	[Assigned by ATSC]
0x0002	<b>Long-form Virtual Channel Table</b> with <code>current_next_indicator=1</code>
0x0003	<b>Long-form Virtual Channel Table</b> with <code>current_next_indicator=0</code>
0x0004	[Assigned by ATSC]
0x0005-0x000F	[Reserved]
0x0010	<b>Short-form Virtual Channel Table—VCM Subtype</b>
0x0011	<b>Short-form Virtual Channel Table—DCM Subtype</b>
0x0012	<b>Short-form Virtual Channel Table—ICM Subtype</b>
0x0013-0x01F	[Reserved]
0x0020	<b>Network Information Table—CDS Table Subtype</b>
0x0021	<b>Network Information Table—MMS Table Subtype</b>
0x0021-0x02F	[Reserved]
0x0030	<b>Network Text Table—SNS Subtype</b>
0x0031-0x00FF	[Reserved]
0x0100-0x017F	[Assigned by ATSC]
0x0180-0x01FF	[Reserved]
0x0200-0x027F	[Assigned by ATSC]
0x028F-0x0300	[Reserved]
0x0301-0x03FF	<b>Rating Region Table with rating_region 1-255</b>
0x0400-0x0FFF	[User private]
0x1000-0x10FF	<b>Aggregate Event Information Table with MGT_tag 0 to 255</b>
0x1100-0x11FF	<b>Aggregate Extended Text Table with MGT_tag 0 to 255</b>
0x1200-0xFFFF	[Reserved]

For table types formatted with the MPEG short-form syntax, the `revision_detection_descriptor()` shall be used to indicate the section number and version. For example, `table_type 0x0020` indicates the Network Information Table, CDS table subtype. One MGT reference to CDS would cover all sections of the delivered CDS.

MGT table types 0x1000 through 0x10FF reference AEIT instances with `MGT_tag` values 0x00 through 0xFF, respectively. Table types 0x1100 through 0x11FF reference AETT instances with `MGT_tag` values 0x00 through 0xFF, respectively. A `table_type` value of 0x1023 in the MGT, for example, refers to the instance of the AEIT with `MGT_tag` value 0x23.

Note that the choice of value of the `MGT_tag` is independent of the timeslot number. For example, the `MGT_tag` value used to deliver AEIT-0 may be zero or any other value up to 255.

**table\_type\_PID** — This 13-bit field specifies the PID for the `table_type` described in the loop.

**table\_type\_version\_number**— This 5-bit field reflects the version number of the `table_type` described in the loop. The value of this field shall be the same as the `version_number` entered in the corresponding fields of tables and table instances. The version number for the next L-VCT (`current_next_indicator = 0`) shall be one unit more (modulo 32) than the version number for the current L-VCT (`current_next_indicator = 1`).

**number\_bytes** — This 32-bit unsigned integer field indicates the total number of bytes used for the `table_type` described in the loop. There may be more than one instance of the indicated `table_type`.

**table\_type\_descriptors\_length** — Total length of the descriptors for the `table_type` described in the loop (in bytes).

**descriptors\_length** — Total length of the MGT descriptor list that follows (in bytes).

**descriptor()** — The table section may include, at its end, one or more structures of the form tag, length, data. Descriptors are defined in Section 6.

**CRC\_32** — This is a 32-bit field that contains the CRC value to ensure a zero output from the registers in the decoder defined in Annex A of ISO/IEC 13818-1 “MPEG-2 Systems” after processing the entire Master Guide Table section.

#### 5.5.1 Restrictions on PID Values

Certain restrictions apply to the PID values specified in the MGT. These restrictions are necessary to ensure the Host can collect EPG data using a minimum number of concurrent flows on the Extended Channel.

- All AEIT and AETT table sections with common `MGT_tag` values shall share a common PID.
- AEIT-0, AETT-0, AEIT-1 and AETT-1 instances shall share a common PID value.<sup>6</sup>
- AEIT-2, AETT-2, AEIT-3 and AETT-3 instances shall be associated with a second separate PID value.
- EPG data describing events farther into the future may be associated with one or more PID values; the second PID value may be used for all or some of the AEIT/AETT-4 through AEIT/AETT-N instances ( $N < 256$ ).

#### 5.5.2 Restrictions on Order of Occurrence of Table References

For all table references except AEIT and AETT, the order of appearance in the MGT of various table references is not specified or restricted. For AEIT and AETT references, the following restriction applies:

- The order of appearance of AEIT/AETT references in the MGT shall correspond to increasing time slot assignments.

---

<sup>6</sup> Please refer to Sec. 5.8 on page 45 for definition of the AEIT-*n* and AETT-*n* notation convention used in this document.

*Note:* this rule allows a Host to know, before processing the AEIT/AETT data which table instances correspond to near-term data and which correspond to data farther into the future. This information is useful if the Host has insufficient RAM to hold all data transmitted.

### 5.6 Long-form Virtual Channel Table

The Long-form Virtual Channel Table is carried in MPEG-2 table sections with table ID 0xC9, and conforms to the syntax and semantics of the MPEG-2 Private Section as described in Section 2.4.4.10 and 2.4.4.11 of ISO/IEC 13818-1. The sections of the Long-form Virtual Channel Table shall be associated on an Extended Channel Interface with PID value 0x1FFC, the SI\_base PID.

The bit stream syntax for the Long-form Virtual Channel Table is shown in Table 5.26.

**table\_id** — An 8-bit unsigned integer number that indicates the type of table section being defined here. For the `longform_virtual_channel_table_section`, the `table_id` shall be 0xC9.

**section\_syntax\_indicator** — The `section_syntax_indicator` is a one-bit field which shall be set to ‘1’ for the `longform_virtual_channel_table_section()`.

**private\_indicator** — This 1-bit field shall be set to ‘1’.

**section\_length** — This is a twelve bit field that specifies the number of bytes of the section, starting immediately following the `section_length` field, and including the CRC. The value in this field shall not exceed 4093.

**map\_ID** — A 16-bit identifier for this Long-form Virtual Channel Table. In some applications, the POD module may receive multiple Long-form Virtual Channel Table sections corresponding to distinct channel maps. In this case, the POD may use the `map_ID` to distinguish them, using information provided outside the scope of this standard. In every case, the Host will receive just one L-VCT across the POD to Host interface, and the `map_ID` parameter may be ignored.

**version\_number** — This 5 bit field is the version number of the Long-form Virtual Channel Table. For the current L-VCT (`current_next_indicator` = 1), the version number shall be incremented by 1 whenever the value of the current L-VCT changes. Upon reaching the value 31, it wraps around to 0. For the next L-VCT (`current_next_indicator` = 0), the version number shall be one unit more than that of the current L-VCT (also in modulo 32 arithmetic). In any case, the value of the `version_number` shall be identical to that of the corresponding entries in the MGT.

**current\_next\_indicator** — A one-bit indicator, which when set to ‘1’ indicates that the Long-form Virtual Channel Table sent is currently applicable. When the bit is set to ‘0’, it indicates that the table sent is not yet applicable and shall be the next table to become valid.

**section\_number** — This 8 bit field gives the number of this section. The `section_number` of the first section in the Long-form Virtual Channel Table shall be 0x00. It shall be incremented by one with each additional section in the Long-form Virtual Channel Table.

**last\_section\_number** — This 8 bit field specifies the number of the last section (that is, the section with the highest `section_number`) of the complete Long-form Virtual Channel Table.

**Table 5.26 Long-form Virtual Channel Table section format**

Syntax	Bits	Bytes	Format
<b>longform_virtual_channel_table_section () {</b>			
<b>table_id</b>	8	1	0xC9

<b>descriptors()</b>			
}			
}			
<b>reserved</b>	6	2	'111111'
<b>additional_descriptors_length</b>	10		uimsbf
for(j=0; j<N;j++) {			
<b>additional_descriptors()</b>		var	
}			
<b>CRC_32</b>	32	4	rpchof
}			

**protocol\_version** — An 8-bit unsigned integer field whose function is to allow, in the future, this table type to carry parameters that may be structured differently than those defined in the current protocol. At present, the only valid value for **protocol\_version** is zero. Non-zero values of **protocol\_version** may only be processed by Hosts designed to accommodate the later versions as they become standardized.

**num\_channels\_in\_section**— This 8 bit field specifies the number of virtual channels in the L-VCT section. The number is limited by the section length.

**short\_name**— The name of the virtual channel, represented as a sequence of one to seven 16-bit character codes coded in accordance with the Basic Multilingual Plane (BMP) of Unicode™, as specified in ISO 10646-1. If the name of the virtual channel is shorter than seven Unicode™ characters, one or more instances of the null character value 0x0000 shall be used to pad the string to its fixed 14-byte length.

**major\_channel\_number, minor\_channel\_number** — These two 10-bit fields represent either a two-part or a one-part virtual channel number associated with the virtual channel being defined in this iteration of the “for” loop. One-part numbers range from 0 to 16,383. Two-part numbers consist of a major and a minor number part; the range of each is 0 to 999. The one- or two-part number acts as the user’s reference number for the virtual channel. Some channels may be represented with a one-part number while others in the VCT are represented with two-part numbers.

The six MSBs of the `major_channel_number` field, when all 1, indicate that a one-part number is being specified. The value of the one-part number is given, in C syntax, by:

$$\text{one\_part\_number} = (\text{major\_channel\_number} \& 0x00F) \ll 10 + \text{minor\_channel\_number}$$

When the six MSBs of the `major_channel_number` field are not all 1, and the 10-bit `major_channel_number` field is less than 1000, two fields specify a two-part channel number. The value of the two-part number is given by `major_channel_number` and `minor_channel_number`.

Table 5.27 summarizes the coding of the `major_channel_number` and `minor_channel_number` fields.

**Table 5.27 Major and Minor Channel Number Field Coding**

	20-bit major/minor field (10-bit major + 10-bit minor)		User Channel Number
	Major Number (10 bits)	Minor Number (10 bits)	Two-part user channel number
<b>Two-part channel numbers</b>  (1000 major numbers, each with 1000 minor numbers)	000d	000d	0-0
	000d	001d	0-1
	...	...	...
	000d	999d	0-999
	001d	000d	1-0
	...	...	...
	999d	999d	999-999
[Reserved]	000d to 999d	1000d-1023d	N/A
	1000-1007d	All values	N/A
<b>One-part channel numbers</b>  (16,383 linear space numbers)	6-bit flag (set = 111111b)	One-Part Number (14 bits)	One-part user channel number
	set	0d	0
	set	1d	1
	set	...	...
	set	16383d	16383

**modulation\_mode** — An 8-bit unsigned integer number that indicates the modulation mode for the transmitted carrier associated with this virtual channel. Values of `modulation_mode` are defined by this standard in Table 5.28. For digital signals, the standard values for modulation mode (values below 0x80) indicate transport framing structure, channel coding, interleaving, channel modulation, forward error correction, symbol rate, and other transmission-related parameters, by means of a reference to an appropriate standard. Values of `modulation_mode` 0x80 and above are outside the scope of SCTE. These may be used to specify non-standard modulation modes in private systems. A value of 0x80 for `modulation_mode` indicates that modulation parameters are specified in a private descriptor. The `modulation_mode` field shall be disregarded for inactive channels.

**carrier\_frequency**— A 32-bit unsigned integer that represents the carrier frequency associated with the analog or digital transmission associated with this virtual channel, in Hz. For QAM-modulated signals, the given `carrier_frequency` represents the location of the digitally modulated carrier; for VSB-modulated signals, the given `carrier_frequency` represents the location of the pilot tone; for analog signals, it represents the frequency of the picture carrier. The `carrier_frequency` field shall be disregarded for inactive channels.

**Table 5.28 Modulation Modes**

<b>modulation_mode</b>	<b>meaning</b>
0x00	[Reserved]
0x01	<b>analog</b> — The virtual channel is modulated using standard analog methods for analog television.
0x02	<b>SCTE_mode_1</b> — The virtual channel has a symbol rate of 5.057 Msps, transmitted in accordance with <i>Digital Transmission Standard for Cable Television</i> , Ref. [4] (Mode 1). Typically, mode 1 will be used for 64-QAM.
0x03	<b>SCTE_mode_2</b> — The virtual channel has a symbol rate of 5.361 Msps, transmitted in accordance with <i>Digital Transmission Standard for Cable Television</i> , Ref. [4] (Mode 2). Typically, mode 2 will be used for 256-QAM.
0x04	<b>ATSC (8 VSB)</b> — The virtual channel uses the 8-VSB modulation method conforming to the <i>ATSC Digital Television Standard</i> , Ref [3].
0x05	<b>ATSC (16 VSB)</b> — The virtual channel uses the 16-VSB modulation method conforming to the <i>ATSC Digital Television Standard</i> , Ref [3].
0x06-0x7F	[Reserved for future use]
0x80	Modulation parameters are defined by a private descriptor
0x81-0xFF	[User Private]

**channel\_TSID**— A 16-bit unsigned integer field, in the range 0x0000 to 0xFFFF, that represents the MPEG-2 Transport Stream ID associated with the Transport Stream carrying the MPEG-2 program referenced by this virtual channel. For inactive channels, `channel_TSID` represents the ID of the Transport Stream that will carry the service when it becomes active. The Host may use the `channel_TSID` to verify that a TS acquired at the referenced carrier frequency is actually the desired multiplex. Analog signals may have a TSID provided that it is different from any DTV Transport Stream identifier; that is, it shall be truly unique if present.<sup>7</sup> A value of 0xFFFF for `channel_TSID` shall be specified for analog channels that do not have a valid TSID.

**program\_number** — A 16-bit unsigned integer number that associates the virtual channel being defined here with the MPEG-2 Program Association and TS Program Map tables. For virtual channels representing analog services, a value of 0xFFFF shall be specified for `program_number`. For inactive channels (those not currently present in the Transport Stream), `program_number` shall be set to zero. This number shall **not** be interpreted as pointing to a Program Map Table entry.

**access\_controlled** — A 1-bit Boolean flag, when set, indicates that events associated with this virtual channel may be access controlled. When the flag is set to 0, event access is not restricted.

**hidden** — A 1-bit Boolean flag that indicates, when set, that the virtual channel is not accessed by the user by direct entry of the virtual channel number. Hidden virtual channels are skipped when the user is channel surfing, and appear as if undefined, if accessed by direct channel entry.

<sup>7</sup> A method to include such a unique 16-bit “Transmission Signal ID” in the NTSC VBI is specified in CEA-608-C [15].

Typical applications for hidden channels are test signals and NVOD services. Whether a hidden channel and its event may appear in EPG displays depends on the state of the `hide_guide` bit.

**path\_select** — A 1-bit field that associates the virtual channel with a transmission path. Two paths are available as defined in Table 5.29 below. For the cable transmission medium, `path_select` identifies which of two physical input cables carries the Transport Stream associated with this virtual channel.

**Table 5.29 Path Select**

<code>path_select</code>	Meaning
0	path 1
1	path 2

**out\_of\_band** — A Boolean flag that indicates, when set, that the virtual channel defined in this iteration of the “for” loop is carried on the cable on the Extended Channel interface carrying the tables defined in this protocol. When clear, the virtual channel is carried within a standard tuned multiplex at that frequency.

*Note:* A virtual channel carried on the out-of-band channel may be acquired by opening a flow between Host and POD to capture the PAT on PID 0. Processing the PAT will determine the PID associated with that service’s PMT. Then, a flow can be opened to capture and process the PMT to determine the PIDs associated with elementary stream components of the service. Finally, a flow associated with the service’s PID can be opened to capture service-related data.

**hide\_guide** — A Boolean flag that indicates, when set to 0 for a hidden channel, that the virtual channel and its events may appear in EPG displays. This bit shall be ignored for channels which do not have the `hidden` bit set, so that non-hidden channels and their events may always be included in EPG displays regardless of the state of the `hide_guide` bit. Typical applications for hidden channels with the `hide_guide` bit set to 1 are test signals and services accessible through application-level pointers.

An *inactive channel* is defined as a channel that has program guide data available, but the channel is not currently on the air. Inactive channels are represented as hidden channels with the `hide_guide` bit set to 0. The Transport Stream shall not carry a Program Map Table representing an inactive channel.

**service\_type**— A 6-bit enumerated type field that identifies the type of service carried in this virtual channel, based on Table 5.30.

**Table 5.30 Service Types**

<b>service_type</b>	<b>Meaning</b>
0x00	[Reserved]
0x01	<b>analog_television</b> — The virtual channel carries analog television programming
0x02	<b>ATSC_digital_television</b> — The virtual channel carries television programming (audio, video and data) conforming to the ATSC Digital Television Standard
0x03	<b>ATSC_audio_only</b> — The virtual channel conforms to the ATSC Digital Television Standard, and has one or more standard audio and data components but no video.
0x04	<b>ATSC_data_broadcast_service</b> — Conforming to the ATSC data broadcast standard under development by T3/S13.
0x05-0x3F	[Reserved for future ATSC use]

**source\_id** — A 16-bit unsigned integer number that identifies the programming source associated with the virtual channel. In this context, a *source* is one specific source of video, text, data, or audio programming. Source ID value zero is reserved to indicate that the programming source is not identified. Source ID values in the range 0x0001 to 0x0FFF shall be unique within the Transport Stream that carries the VCT, while values 0x1000 to 0xFFFF shall be unique at the regional level. Values for `source_ids` 0x1000 and above shall be issued and administered by a Registration Authority designated by the ATSC.

**descriptors\_length** — Total length (in bytes) of the descriptors for this virtual channel that follows.

**additional\_descriptors\_length** — Total length (in bytes) of the VCT descriptor list that follows.

**CRC\_32** — This is a 32-bit field that contains the CRC value that ensures a zero output from the registers in the decoder defined in Annex A of ISO/IEC 13818-1 “MPEG-2 Systems” after processing the entire Long-form Virtual Channel Table section.

For inactive channels, the `short_name`, `major_channel_number`, and `minor_channel_number` fields reflect the name and channel number of the inactive channel, and may be used in construction of the program guide. The `source_id` for inactive channels is used, as it is for active channels, to link the virtual channel to the program guide data. The `service_type` field and attribute flags reflect the characteristics of the channel that will be valid when it is active.

### 5.7 Rating Region Table (RRT)

The Rating Region Table carries rating information for multiple geographical regions. The RRT shall be associated on an Extended Channel Interface with PID value 0x1FFC, the `SI_base` PID.

Transmission of the RRT is required whenever any Transport Stream carries a service that includes a `content_advisory_descriptor()` in one of its Program Map Tables, or if a `content_advisory_descriptor()` appears in any transmitted AEIT. An instance of the RRT for each region referenced in any `content_advisory_descriptor()` shall be transmitted.

Each RRT instance, identified by `rating_region` (the eight least significant bits of `table_id_extension`), conveys the rating system information for one specific region. The size of each RRT instance shall not be more than 1,024 bytes (including section header and trailer), and it shall be carried by only one MPEG-2 private section.

Table 5.31 describes the Rating Region Table.

**table\_ID** — The table\_ID of the Rating Region Table (RRT) shall be 0xCA.

**section\_syntax\_indicator** — This 1-bit field shall be set to ‘1’. It denotes that the section follows the generic section syntax beyond the section length field.

**private\_indicator** — This 1-bit field shall be set to ‘1’.

**Table 5.31 Rating Region Table section format**

	Bits	Bytes	Format
<b>rating_region_table_section () {</b>			
<b>table_ID</b>	8	1	0xCA
<b>section_syntax_indicator</b>	1	2	‘1’
<b>private_indicator</b>	1		‘1’
<b>reserved</b>	2		‘11’
<b>section_length</b>	12		uimsbf
table_ID_extension{			
<b>reserved</b>	8	1	0xFF
<b>rating_region</b>	8	1	uimsbf
}			
<b>reserved</b>	2	1	‘11’
<b>version_number</b>	5		uimsbf
<b>current_next_indicator</b>	1		‘1’
<b>section_number</b>	8	1	uimsbf
<b>last_section_number</b>	8	1	uimsbf
<b>protocol_version</b>	8	1	uimsbf
<b>rating_region_name_length</b>	8	1	uimsbf
<b>rating_region_name_text()</b>	var		
<b>dimensions_defined</b>	8	1	uimsbf
for(i=0; i<dimensions_defined;i++) {			
<b>dimension_name_length</b>	8	1	uimsbf
<b>dimension_name_text()</b>	var		
<b>reserved</b>	3	1	‘111’
<b>graduated_scale</b>	1		bslbf
<b>values_defined</b>	4		uimsbf
for (j=0;j<values_defined;j++) {			
<b>abbrev_rating_value_length</b>	8	1	uimsbf
<b>abbrev_rating_value_text()</b>	var		
<b>rating_value_length</b>	8	1	uimsbf
<b>rating_value_text()</b>	var		
}			
}			
<b>reserved</b>	6	2	‘111111’
<b>descriptors_length</b>	10		uimsbf
for (i=0;i<N;i++) {			
<b>descriptors()</b>	var		
}			
<b>CRC_32</b>	32	4	rpchof
}			

**section\_length** — 12-bit field specifying the number of remaining bytes in this section immediately following the section\_length field up to the end of the section. The value of the section\_length shall be no larger than 1,021.

**rating\_region** — An 8-bit unsigned integer number that defines the rating region to be associated with the text in this rating\_region\_table\_section(). The value of this field is the identifier of this rating

region, and thus this field may be used by the other tables (e.g. MGT) for referring to a specific rating region table. Values of `rating_region` are defined in Table 5.32.

**Table 5.32 Rating Regions**

<b>rating_region</b>	<b>Rating Region Name</b>
0x00	Forbidden
0x01	<b>US (50 states + possessions)</b>
0x02-0xFF	[Reserved]

**version\_number** — This 5-bit field is the version number of the Rating Region Table identified by combination of the fields `table_ID` and `table_ID_extension`. The version number shall be incremented by 1 modulo 32 when any field in this instance of the Rating Region Table changes. The value of this field shall be the same as that of the corresponding entry in MGT.

**current\_next\_indicator** — This 1-bit indicator is always set to ‘1’.

**section\_number** — The value of this 8-bit field shall always be 0x00.

**last\_section\_number** — The value of this 8-bit field shall always be 0x00.

**protocol\_version** — The value of this 8-bit field shall always be 0x00.

**rating\_region\_name\_length** — An 8-bit unsigned integer number that defines the total length (in bytes) of the `rating_region_name_text()` field to follow.

**rating\_region\_name\_text()** — A data structure containing a Multiple String Structure which represents the rating region name, e.g. “U.S. (50 states + possessions)”, associated with the value given by `rating_region`. The `rating_region_name_text()` shall be formatted according to the Multiple String Structure (see Section 7.2). The display string for the rating region name shall be limited to 32 characters or less.

**dimensions\_defined** — This 8-bit field (1-255) specifies the number of dimensions defined in this `rating_region_table_section()`.

**dimension\_name\_length** — An 8-bit unsigned integer number that defines the total length in bytes of the `dimension_name_text()` field to follow.

**dimension\_name\_text()** — A data structure containing a Multiple String Structure which represents the dimension name being described in the loop. One dimension in the U.S. rating region, for example, is used to describe the MPAA list. The dimension name for such a case may be defined as “MPAA”. The `dimension_name_text()` shall be formatted according to the Multiple String Structure (see Section 7.2). The dimension name display string shall be limited to 20 characters or less.

**graduated\_scale** — This 1-bit flag indicates whether or not the rating values in this dimension represent a graduated scale, i.e., higher rating values represent increasing levels of rated content within the dimension. Value 1 means yes, while value 0 means no.

**values\_defined** — This 4-bit field (1-15) specifies the number of values defined for this particular dimension.

**abbrev\_rating\_value\_length** — An 8-bit unsigned integer number that defines the total length (in bytes) of the `abbrev_rating_value_text()` field to follow.

**abbrev\_rating\_value\_text()** — A data structure containing a Multiple String Structure which represents the abbreviated name for one particular rating value. The abbreviated name for rating value 0 shall be set to a null string, i.e., “”. The `abbrev_rating_value_text()` shall be formatted according to the Multiple String Structure (see Section 7.2). The abbreviated value display string shall be limited to 8 characters or less.

**rating\_value\_length** — An 8-bit unsigned integer number that defines the total length (in bytes) of the `rating_value_text()` field to follow.

**rating\_value\_text()** — A data structure containing a Multiple String Structure which represents the full name for one particular rating value. The full name for rating value 0 shall be set to a null string, i.e., “”. The `rating_value_text()` shall be formatted according to the Multiple String Structure (see Section 7.2). The rating value display string shall be limited to 150 characters or less.

**descriptors\_length** — Length (in bytes) of all of the descriptors that follow this field.

**CRC\_32** — This is a 32-bit field that contains the CRC value that ensures a zero output from the registers in the decoder defined in Annex A of ISO/IEC 13818-1 “MPEG-2 Systems” after processing the entire Rating Region Table section.

## 5.8 Aggregate Event Information Tables (AEIT)

The Aggregate Event Information Table delivers event title and schedule information that may be used to support an Electronic Program Guide application. The transmission format allows instances of table sections for different time periods to be associated with common PID values. Reducing the total number of PID values in use over an Extended Channel Interface is important, because the POD module can typically support only a small number of concurrent data flows (each associated with one PID value).

Each AEIT instance describes event data for one three-hour time period. The start time for any AEIT is constrained to be one of the following eight UTC times: 00:00 (midnight), 03:00, 06:00, 09:00, 12:00 (noon), 15:00, 18:00, and 21:00.

The notation `AEIT-n` refers to the AEIT corresponding to timeslot *n*. Value 0 for *n* indicates the current timeslot, value 1 the next timeslot, etc. The same notational methods apply to AETT.

Except for AEIT-0, each AEIT instance shall include event data only for those events actually starting within the covered time period.<sup>8</sup> AEIT-0 shall also include event data for all events starting in a prior timeslot but continuing into the current timeslot. In addition, if the VCT entry for a particular source ID includes a `time_shifted_service_descriptor()`, AEIT-0 shall describe event data for active events on any channels referenced through the `time_shifted_service_descriptor()`.

ETMs for events described in AEIT-0 shall be provided in AETT-0 on the PID associated with AEIT-0 until they are no longer referenced by AEIT-0.

---

<sup>8</sup> Although AEIT is similar in structure to the EIT in ATSC A/65, its properties differ from EIT in this regard.

Table 5.33 defines the syntax of the Aggregate Event Information Table.

**table\_ID** — The `table_ID` of the Aggregate Event Information Table shall be 0xD6.

**section\_syntax\_indicator** — This 1-bit field shall be set to ‘1’. It denotes that the section follows the generic section syntax beyond the section length field.

**private\_indicator** — This 1-bit field shall be set to ‘1’.

**section\_length** — 12-bit field specifying the number of remaining bytes in this section immediately following the `section_length` field up to the end of the section, including the `CRC_32` field. The value of this field shall not exceed 4,093.

**AEIT\_subtype** — This 8-bit field identifies the subtype of the AEIT. In the current protocol, only table subtype value 0x00 is defined. Host devices shall discard instances of the `aggregate_event_information_table_section()` in which an unknown `AEIT_subtype` is specified (currently, any value other than zero).

**MGT\_tag** — An 8-bit field that ties this AEIT instance to the corresponding `table_type` in the MGT and to an AETT instance with the same value. The `MGT_tag` value for an AEIT instance for a given timeslot shall be one higher (modulo 256) than the instance for the preceding time period.

**version\_number** — This 5-bit field is the version number of the AEIT instance. An instance is identified by the `MGT_tag`. The version number shall be incremented by 1 modulo 32 when any field in the AEIT instance changes. The value of this field shall be identical to that of the corresponding entry in the MGT.

**current\_next\_indicator** — This 1-bit indicator is always set to ‘1’ for AEIT sections; the AEIT sent is always currently applicable.

**section\_number** — This 8-bit field gives the number of this section.

**last\_section\_number** — This 8-bit field specifies the number of the last section.

**num\_sources\_in\_section** — This 8-bit field gives the number of iterations of the “for” loop describing program schedule data.

**source\_ID** — This 16-bit field specifies the `source_ID` of the virtual channel carrying the events described in this section.

**Table 5.33 Aggregate Event Information Table format**

<b>CRC_32</b>	32	4	rpchof
}			

**num\_events** — Indicates the number of events to follow associated with the program source identified by `source_ID`. Value 0 indicates no events are defined for this source for the time period covered by the AEIT instance.

**event\_ID** — This 14-bit field specifies the identification number of the event described. This number serves as a part of the event `ETM_ID` (identifier for event Extended Text Message). An assigned `event_ID` shall be unique at least within the scope of the instance of the AEIT in which it appears. Accordingly, as an example, the event associated with `event_ID 0x0123` in AEIT-m shall be considered to be an event distinct from `event_ID 0x0123` in AEIT-n, when m is not equal to n.

**start\_time** — A 32-bit unsigned integer quantity representing the start time of this event as the number of seconds since 0000 Hours UTC, January 6<sup>th</sup>, 1980. If the `GPS.UTC_offset` delivered in

the System Time Table is zero, `start_time` includes the correction for leap seconds. Otherwise, `start_time` can be converted to UTC by subtracting the `GPS.UTC_offset`.

**ETM\_present** — This 2-bit field indicates the existence of an Extended Text Message (ETM) based on Table 5.34.

**Table 5.34 ETM\_present**

ETM_present	Meaning
0x00	No ETM
0x01	ETM present on this out-of-band Extended Channel
0x02-0x03	[Reserved for future use]

**duration** — Duration of this event in seconds.

**title\_length** — This field specifies the length (in bytes) of the `title_text()`. Value 0 means that no title exists for this event.

**title\_text()** — The event title in the format of a Multiple String Structure. `title_text()` shall be formatted according to the Multiple String Structure (see Section 7.2).

**descriptors\_length** — Total length (in bytes) of the event descriptor list that follows.

**CRC\_32** — This is a 32-bit field that contains the CRC value that ensures a zero output from the registers in the decoder defined in Annex A of ISO-13818-1 “MPEG-2 Systems” after processing the entire Aggregate Event Information Table section.

## 5.9 Aggregate Extended Text Tables (AETT)

The Aggregate Extended Text Table contains Extended Text Messages (ETM), which are used to provide detailed descriptions of events. An ETM is a multiple string data structure. Thus, it may represent a description in several different languages (each string corresponding to one language). If necessary, the description may be truncated to fit the allocated display space.

The transmission format of the AETT and its affiliated AEIT allows instances of AEIT/AETT table sections for different time slots to be associated with common PID values.

AETT-*n* shall be associated with the same PID value as AEIT-*n* for a given value of *n*.

The Aggregate Extended Text Table is carried in an MPEG-2 private section with `table_ID` 0xD7. An instance of the AETT includes one or more ETMs. Each description is distinguished by its unique 32-bit `ETM_ID`.

Table 5.35 defines the syntax of the Aggregate Extended Text Table.

**Table 5.35 Aggregate Extended Text Table format**

Syntax	Bits	Bytes	Format
<b>aggregate_extended_text_table_section () {</b>			
<b>table_ID</b>	8	1	0xD7
<b>section_syntax_indicator</b>	1	2	'1'
<b>private_indicator</b>	1		'1'
<b>reserved</b>	2		'11'
<b>section_length</b>	12		uimsbf
<b>AETT_subtype</b>	8	1	uimsbf
<b>MGT_tag</b>	8	1	uimsbf
<b>reserved</b>	2	1	'11'
<b>version_number</b>	5		uimsbf
<b>current_next_indicator</b>	1		'1'
<b>section_number</b>	8	1	uimsbf
<b>last_section_number</b>	8	1	uimsbf
if (AETT_subtype == 0) {			
<b>num_blocks_in_section</b>	8	1	uimsbf
for (j = 0; j < num_blocks_in_section; j++) {			
<b>ETM_ID</b>	32	(4)	uimsbf
<b>reserved</b>	4	(2)	'1111'
<b>extended_text_length</b>	12		uimsbf
<b>extended_text_message()</b>	var		
}			
}			
else			
<b>reserved</b>	n*8	n	
<b>CRC_32</b>	32	4	rpchof
}			

**table\_ID** — The table\_ID of the Aggregate Extended Text Table shall be 0xD7.

**section\_syntax\_indicator** — This 1-bit field shall be set to '1'. It denotes that the section follows the generic section syntax beyond the section length field.

**private\_indicator** — This 1-bit field shall be set to '1'.

**section\_length** — 12-bit field specifying the number of remaining bytes in the section immediately following the section\_length field up to the end of the section. The value of the section\_length shall be no larger than 4093.

**AETT\_subtype** — This 8-bit field identifies the subtype of the AETT. In the current protocol, only table subtype value 0x00 is defined. Host devices shall discard instances of the aggregate\_extended\_text\_table\_section() in which an unknown AETT\_subtype is specified (currently, any value other than zero).

**MGT\_tag** — An 8-bit field that ties this AETT instance to the corresponding table\_type in the MGT and to an AEIT instance with the same value. The MGT\_tag value for an AETT instance for a given time period shall be one higher (modulo 256) than the instance for the preceding time period.

**version\_number** — This 5-bit field is the version number of the AETT instance. An instance is uniquely identified by its MGT\_tag. The version number shall be incremented by 1 modulo 32 when any field in the AETT instance changes. The value of this field shall be identical to that of the corresponding entry in the MGT.

**current\_next\_indicator** — This 1-bit indicator is always set to ‘1’ for AETT sections; the AETT sent is always currently applicable.

**section\_number** — This 8-bit field gives the number of this section.

**last\_section\_number** — This 8-bit field specifies the number of the last section.

**num\_blocks\_in\_section** — This 8-bit field gives the number of iterations of the “for” loop describing ETM data.

**ETM\_ID** — Unique 32-bit identifier of this Extended Text Message. This identifier is assigned by the rule shown in Table 5.36.

**Table 5.36 ETM ID**

	MSB			LSB	
Bit	31	16	15	2	1 0
event ETM_ID	source_ID		event_ID		1 0

**extended\_text\_length** — A 12-bit unsigned integer number that represents the length, in bytes, of the `extended_text_message()` field directly following.

**extended\_text\_message()** — The extended text message in the format of a Multiple String Structure (see Section 7.2).

**CRC\_32** — This is a 32-bit field that contains the CRC value that ensures a zero output from the registers in the decoder defined in Annex A of ISO-13818-1 “MPEG-2 Systems” after processing the entire Transport Stream AETT section.

## 6 DESCRIPTORS

This section defines descriptors applicable for use with various table sections defined in this standard.

### 6.1 Descriptor Usage

Table 6.1 lists all descriptors, their tag numbers and associated table sections applicable to out-of-band SI transport. Asterisks mark the tables where the descriptors may appear. The range of descriptor tags defined or reserved by MPEG-2 includes those with tag values 0x3F or below, plus 0xFF.

**Table 6.1 Descriptor Usage**

Descriptor Name	Tag	Table Section								
		PMT	NIT	NTT	S-VCT	STT	MG T	L-VCT	RRT	AEI T
stuffing descriptor	0x80	*	*	*	*	*	*	*	*	*
AC-3 audio descriptor	0x81	*								*
Caption service descriptor	0x86	*								*
Content advisory descriptor	0x87	*								*
Revision detection descriptor	0x93		*	*	*					
Two part channel no. descriptor	0x94				*					
Channel properties descriptor	0x95				*					
Daylight savings time descriptor	0x96					*				
Extended channel name descr.	0xA0							*		
Time shifted service descriptor	0xA2							*		
Component name descriptor	0xA3	*								
User private descriptors	0xC0-0xFF		*	*	*	*	*	*	*	*

### 6.2 Stuffing Descriptor

For certain applications it is necessary to define a block of N bytes as a placeholder. The N bytes themselves are not to be processed or interpreted. The `stuffing_descriptor()` is specified for this purpose. The `stuffing_descriptor()` is simply a descriptor type for which the contents, as indicated by the `descriptor_length` field, are to be disregarded. The tag type for the stuffing descriptor is 0x80. The `stuffing_descriptor()` may appear where descriptors are allowed in any table defined in this standard.

### 6.3 AC-3 Audio Descriptor

The AC-3 audio descriptor, as defined in Ref. [2] and constrained in Annex B of Ref. [3], may be used in the PMT and/or in AEITs.

### 6.4 Caption Service Descriptor

The caption service descriptor provides closed captioning information, such as closed captioning type and language code for events with closed captioning service. This descriptor shall not appear on events with no closed captioning service.

The bit stream syntax for the Caption Service Descriptor is shown in Table 6.2.

**Table 6.2 Caption Service Descriptor format**

Syntax	Bits	Bytes	Format
<b>caption_service_descriptor()</b> {			
<b>descriptor_tag</b>	8	1	0x86
<b>descriptor_length</b>	8	1	uimsbf
<b>reserved</b>	3	1	'111'
<b>number_of_services</b>	5		uimsbf
for (i=0;i<number_of_services;i++) {			
<b>language</b>	8*3	(3)	uimsbf
<b>cc_type</b>	1	(1)	bslbf
<b>reserved</b>	1		'1'
if (cc_type==line21) {			
<b>reserved</b>	5		'11111'
<b>line21_field</b>	1		bslbf
}			
else			
<b>caption_service_number</b>	6		uimsbf
<b>easy_reader</b>	1	(2)	bslbf
<b>wide_aspect_ratio</b>	1		bslbf
<b>reserved</b>	14		'11111111111111'
}			
}			

**descriptor\_tag** — An 8-bit field that identifies the type of descriptor. For the `caption_service_descriptor()` the value is 0x86.

**descriptor\_length** — An 8-bit count of the number of bytes following the `descriptor_length` itself.

**number\_of\_services** — An unsigned 5-bit integer in the range 1 to 16 that indicates the number of closed caption services present in the associated video service. Note that if the video service does not carry television closed captioning, the `caption_service_descriptor()` shall not be present either in the Program Map Table or in the Aggregate Event Information Table.

Each iteration of the “for” loop defines one closed caption service present as a sub-stream within the 9600 bit per second closed captioning stream. Each iteration provides the sub-stream’s language, attributes, and (for advanced captions) the associated Service Number

reference. Refer to Ref. [13] for a description of the use of the Service Number field within the syntax of the closed caption stream.

**language** — A 3-byte language code per ISO 639.2/B (Ref. [8]) defining the language associated with one closed caption service. The `ISO_639_language_code` field contains a three-character code as specified by ISO 639.2/B. Each character is coded into 8 bits according to ISO 8859-1 (ISO Latin-1) and inserted in order into the 24-bit field.

**cc\_type** — A flag that indicates, when set, that an advanced television closed caption service is present in accordance with Ref. [13]. When the flag is clear, a line-21 closed caption service is present. For line 21 closed captions, the `line21_field` indicates whether the service is carried in the even or odd field.

**line21\_field** — A flag that indicates, when set, that the line 21 closed caption service is associated with the field 2 of the NTSC waveform. When the flag is clear, the line-21 closed caption service is associated with field 1 of the NTSC waveform. The `line21_field` flag is defined only if the `cc_type` flag indicates line-21 closed caption service.

**caption\_service\_number** — A 6-bit unsigned integer value in the range zero to 63 that identifies the Service Number within the closed captioning stream that is associated with the language and attributes defined in this iteration of the “for” loop. See Ref. [13] for a description of the use of the Service Number. The `caption_service_number` field is defined only if the `cc_type` flag indicates closed captioning in accordance with Ref. [13].

**easy\_reader** — A Boolean flag which indicates, when set, that the closed caption service contains text tailored to the needs of beginning readers. Refer to Ref. [13] for a description of “easy reader” television closed captioning services. When the flag is clear, the closed caption service is not so tailored.

**wide\_aspect\_ratio** — A Boolean flag which indicates, when set, that the closed caption service is formatted for displays with 16:9 aspect ratio. When the flag is clear, the closed caption service is formatted for 4:3 display, but may be optionally displayed centered within a 16:9 display.

## 6.5 Content Advisory Descriptor

The `content_advisory_descriptor()` is used to indicate, for a given event, ratings for any or all of the rating dimensions defined in the RRT (Rating Region Table). Ratings may be given for any or all of the defined regions, up to a maximum of 8 regions per event. An event without a `content_advisory_descriptor()` indicates that the rating value for any rating dimension defined in any rating region is zero. The absence of ratings for a specific dimension is completely equivalent to having a zero-valued rating for such a dimension. The absence of ratings for a specific region implies the absence of ratings for all of the dimensions in the region. The absence of a `content_advisory_descriptor()` for a specific event implies the absence of ratings for all of the regions for the event. The bit stream syntax for the `content_advisory_descriptor()` is shown in Table 6.3.

**descriptor\_tag** — This 8-bit unsigned integer shall have the value 0x87, identifying this descriptor as `content_advisory_descriptor`.

**Table 6.3 Content Advisory Descriptor format**

Syntax	Bits	Bytes	Format
<b>content_advisory_descriptor()</b> {			
<b>descriptor_tag</b>	8	1	0x87
<b>descriptor_length</b>	8	1	uimsbf
<b>reserved</b>	2	1	'11'
<b>rating_region_count</b>	6		
for (i=0; i<rating_region_count; i++) {			
<b>rating_region</b>	8	1	uimsbf
<b>rated_dimensions</b>	8	1	uimsbf
for (j=0; j<rated_dimensions; j++) {			
<b>rating_dimension_j</b>	8	1	uimsbf
<b>reserved</b>	4	1	'1111'
<b>rating_value</b>	4		uimsbf
}			
<b>rating_description_length</b>	8	1	uimsbf
<b>rating_description_text()</b>	var		
}			
}			

**descriptor\_length** — This 8-bit unsigned integer specifies the length (in bytes) immediately following this field up to the end of this descriptor.

**rating\_region\_count** — A 6-bit unsigned integer value in the range 1 to 8 that indicates the number of rating region specifications to follow.

**rating\_region** — An unsigned 8-bit integer that specifies the rating region for which the data in the bytes to follow is defined. The `rating_region` associates ratings data given here with data defined in a Ratings Region Table tagged with the corresponding rating region.

**rated\_dimensions** — An 8-bit unsigned integer field that specifies the number of rating dimensions for which content advisories are specified for this event. The value of this field shall not be greater than the value specified by the field `dimensions_defined` in the corresponding RRT section.

**rating\_dimension\_j** — An 8-bit unsigned integer field specifies the dimension index into the RRT instance for the region specified by the field `rating_region`. These dimension indices shall be listed in numerical order, i.e., the value of `rating_dimension_j+1` shall be greater than that of `rating_dimension_j`.

**rating\_value** — A 4-bit field represents the rating value of the dimension specified by the field `rating_dimension_j` for the region given by `rating_region`.

**rating\_description\_length** — An 8-bit unsigned integer value in the range zero to 80 that represents the length of the `rating_description_text()` field to follow.

**rating\_description\_text()** — The rating description in the format of a Multiple String Structure (see Section 7.2). The `rating_description` display string shall be limited to 16 characters or less. The rating description text shall represent the program's rating in an abbreviated form suitable for on-screen display. The rating description text collects multidimensional text information into a single small text string. If "xxx" and "yyy" are abbreviated forms for rating values in two dimensions, then "xxx-yyy" and "xxx (yyy)" are examples of possible strings represented in `rating_description_text()`.

The program source provider shall be the responsible party for insertion of correct content\_advisory\_descriptors in the Program Map Table (PMT). Also, the content\_advisory\_descriptors may be included in Aggregate Event Information Tables. If content\_advisory\_descriptors are available both in AEIT and PMT, the PMT should be used first, then the AEITs.

### 6.6 Revision Detection Descriptor

The revision\_detection\_descriptor() is used to indicate whether new information is contained in the table section in which it appears.

Table 6.4 describes the revision\_detection\_descriptor. This descriptor should be the first descriptor in the list to limit processing overhead.

**Table 6.4 Revision Detection Descriptor format**

	Bits	Bytes	Format
revision_detection_descriptor(){			
descriptor_tag	8	1	uimsbf value 0x93
descriptor_length	8	1	uimsbf
reserved	3	1	bslbf
table_version_number	5		uimsbf range 0–31
section_number	8	1	uimsbf range 0–255
last_section_number	8	1	uimsbf range 0–255
}			

**descriptor\_tag**—An 8-bit unsigned integer number that identifies the descriptor as a revision\_detection\_descriptor(). The tag shall have the value 0x93.

**descriptor\_length**—An 8-bit unsigned integer number that indicates the number of bytes to follow in the descriptor. At present, just three bytes are defined, but the length field shall be processed to allow new data to be added to the descriptor in the future.

**table\_version\_number**—this 5-bit unsigned integer in the range 0 to 31 identifies the version of the current table. This integer applies only to the table (or the section of it) currently transmitted. Other types of tables may have different version numbers. To indicate a change in a specific table, this integer is incremented by 1 modulo 32.

**section\_number**—An 8-bit unsigned integer in the range 0 to 255 that identifies the current table section. Version numbers for all sections of a table must be the same. Note that section\_number = 0 indicates the first section of a table.

**last\_section\_number**— An 8-bit unsigned integer in the range 0 to 255 that identifies the number of sections in a table. Note that if the last\_section\_number = 0, then there is only one section in this table.

### 6.7 Two Part Channel Number Descriptor

Table 6.5 describes the two\_part\_channel\_number\_descriptor(). This descriptor may appear in the virtual\_channel() record, contained in the VCM\_structure; within the Short-form Virtual Channel Table section. The descriptor may be used by compatible Hosts to associate a two-part user channel number with any virtual channel. Some channels may have a two\_part\_channel\_number\_descriptor() while others do not.

*Note:* For the L-VCT, the 10-bit major/minor number fields can be coded to represent a one-part channel number. The one-part representation is not needed for the major/minor number fields in the `two_part_channel_number_descriptor()` in the S-VCT, because there is already a 12-bit one-part number on each channel in S-VCT. It would cause confusion to allow a second one-part number to be associated with a channel defined in S-VCT.

**Table 6.5 Two-part Channel Number Descriptor format**

	Bits	Bytes	Format
<code>two_part_channel_number_descriptor(){</code>			
<b>descriptor_tag</b>	8	1	uimsbf value 0x94
<b>descriptor_length</b>	8	1	uimsbf
<b>reserved</b>	6	2	bslbf
<b>major_channel_number</b>	10		uimsbf range 0-999
<b>reserved</b>	6	2	bslbf
<b>minor_channel_number</b>	10		uimsbf range 0-999
<code>}</code>			

**descriptor\_tag**—An 8-bit unsigned integer number that identifies the descriptor as a `two_part_channel_number_descriptor()`. The tag shall have the value 0x94.

**descriptor\_length**—An 8-bit unsigned integer number that indicates the number of bytes to follow in the descriptor. At present, just four bytes are defined, but the length field shall be processed to allow new data to be added to the descriptor in the future.

**major\_channel\_number**—A 10-bit unsigned integer in the range 0 to 999 that identifies the “major” channel number to be associated with the virtual channel.

**minor\_channel\_number**—A 10-bit unsigned integer in the range 0 to 999 that identifies the “minor” channel number to be associated with the virtual channel.

Hosts that support two-part channel numbering must support this descriptor. It is only mandatory for this descriptor to be sent in the instance where system support of two-part channel numbering is required. This means for `virtual_channel()` records where the Host does not receive the two-part channel number descriptor, that the Host is expected to use the `virtual_channel_number` described in the `virtual_channel()` record in Section 5.3.2.

### 6.8 Channel Properties Descriptor

The `channel_properties_descriptor()` is defined to allow both forms of VCTs (S-VCT and L-VCT) carrying the same properties. Table 6.6 describes the syntax for this descriptor. The descriptor may appear within a `virtual_channel()` record in the Short-form Virtual Channel Table.

**Table 6.6 Channel Properties Descriptor format**

	Bits	Bytes	Format
<b>channel_properties_descriptor(){</b>			
<b>descriptor_tag</b>	8	1	uimbsf value 0x95
<b>descriptor_length</b>	8	1	uimbsf
<b>channel_TSID</b>	16	2	uimbsf
<b>reserved</b>	6	1	'111111'
<b>out_of_band_channel</b>	1		uimbsf
<b>access_controlled</b>	1		uimbsf
<b>hide_guide</b>	1	1	bslbf
<b>reserved</b>	1		'1'
<b>service_type</b>	6		uimbsf
<b>}</b>			

**descriptor\_tag**—An 8-bit unsigned integer number that identifies the descriptor as a `channel_properties_descriptor()`. The tag shall have the value 0x95.

**descriptor\_length**—An 8-bit unsigned integer number that indicates the number of bytes to follow in the descriptor. At present, just four bytes are defined, but the length field shall be processed to allow new data to be added to the descriptor in the future.

**channel\_TSID** — A 16-bit unsigned integer field in the range 0x0000 to 0xFFFF that represents the MPEG-2 Transport Stream ID associated with the Transport Stream carrying the MPEG-2 program referenced by this virtual channel. For inactive channels, `channel_TSID` represents the ID of the Transport Stream that will carry the service when it becomes active. The Host may use the `channel_TSID` to verify that a TS acquired at the referenced carrier frequency is actually the desired multiplex. Analog signals may have a TSID that is different from any MPEG-2 Transport Stream identifier, that is, it shall be truly unique if present. A value of 0xFFFF for `channel_TSID` shall be specified for situations where a valid TSID is not known (reserved as a wildcard capability).

**out\_of\_band** — A Boolean flag that indicates, when set, that the virtual channel associated with this descriptor is carried on the cable on the Extended Channel interface carrying the tables defined in this protocol. When clear, the virtual channel is carried within a standard tuned multiplex at that frequency.

**access\_controlled**—A Boolean flag that indicates, when set, that events associated with this virtual channel may be access controlled. When the flag is zero, event access is not restricted.

**hide\_guide** – A Boolean flag that indicates, when set to 0 for a channel of `channel_type` hidden, that the virtual channel and its events may appear in EPG displays. This bit shall be ignored for channels which are not the hidden type, so that non-hidden channels and their events may always be included in EPG displays regardless of the state of the `hide_guide` bit. Typical applications for hidden channels with the `hide_guide` bit set to 1 are test signals and services accessible through application-level pointers.

**service\_type**— A 6-bit enumerated type field that identifies the type of service carried in this virtual channel. Service type is coded according to Table 5.30.

Hosts may use this descriptor to become aware of aspects of the channel. In the case where this descriptor is not received, the Host must tune the channel and self-discover these aspects of the channel. For example, if this descriptor is not sent, and the channel is access

controlled, the Host must determine when it can obtain access permission (the same as if that bit in the descriptor were set). Similar rules can be applied for service type and `channel_TSID`.

### 6.9 Extended Channel Name Descriptor

The extended channel name descriptor provides the long channel name for the virtual channel containing this descriptor.

The bit stream syntax for the extended channel name descriptor is shown in Table 6.7.

**Table 6.7 Extended Channel Name Descriptor format**

Syntax	Bits	Bytes	Format
<code>extended_channel_name_descriptor() {</code>			
<b>descriptor_tag</b>	8	1	0xA0
<b>descriptor_length</b>	8	1	uimsbf
<b>long_channel_name_text()</b>	var		
<code>}</code>			

**descriptor\_tag** — This 8-bit unsigned integer shall have the value 0xA0, identifying this descriptor as `extended_channel_name_descriptor()`.

**descriptor\_length** — This 8-bit unsigned integer specifies the length (in bytes) immediately following this field up to the end of this descriptor.

**long\_channel\_name\_text()** — The long channel name in the format of a Multiple String Structure (see Section 7.2).

### 6.10 Time Shifted Service Descriptor

This descriptor links one virtual channel with one or more virtual channels that carry the same programming on a time-shifted basis. The typical application is for Near Video On Demand (NVOD) services.

*Note:* For the L-VCT, the 10-bit major/minor number fields can be coded to represent a one-part channel number. The one-part representation is not applicable for the major/minor number fields in the `time_shifted_services_descriptor()` because this descriptor is not applicable to S-VCT (see Table A.2). The major/minor number fields in the `time_shifted_services_descriptor()` are only used to match against fields in the L-VCT.

The bit stream syntax for the `time_shifted_service_descriptor()` is shown in Table 6.8.

**Table 6.8 Time Shifted Service Descriptor format**

Syntax	Bits	Bytes	Format
<b>time_shifted_service_descriptor() {</b>			
<b>descriptor_tag</b>	8	1	0xA2
<b>descriptor_length</b>	8	1	uimsbf
<b>reserved</b>	3	1	'111'
<b>number_of_services</b>	5		uimsbf
for (i=0;i<number_of_services;i++) {			
<b>reserved</b>	6	1	'111111'
<b>time_shift</b>	10	1	uimsbf
<b>reserved</b>	4	2	'1111'
<b>major_channel_number</b>	10		uimsbf
<b>minor_channel_number</b>	10	2	uimsbf
}			
}			

**descriptor\_tag** — This 8-bit unsigned integer shall have the value 0xA2, identifying this descriptor as time\_shifted\_service\_descriptor().

**descriptor\_length** — This 8-bit unsigned integer specifies the length (in bytes) immediately following this field up to the end of this descriptor.

**number\_of\_services** — A 5-bit number in the range 1 to 20 that indicates the number of time-shifted services being defined here.

**time\_shift** — A 10-bit number in the range 1 to 720 that represents the number of minutes the time-shifted service indicated by major\_channel\_number and minor\_channel\_number is time-shifted from the virtual channel associated with this descriptor.

**major\_channel\_number** — A 10-bit number in the range 1 to 999 that represents the “major” channel number associated with a time-shifted service.

**minor\_channel\_number** — A 10-bit number in the range 0 to 999 that, when non-zero, represents the “minor” or “sub-“ channel number of the virtual channel that carries a time-shifted service.

### 6.11 Component Name Descriptor

Table 6.9 defines the component\_name\_descriptor(), which serves to define an optional textual name tag for any component of the service.

**Table 6.9 Component Name Descriptor format**

Syntax	Bits	Bytes	Format
<b>component_name_descriptor() {</b>			
<b>descriptor_tag</b>	8	1	0xA3
<b>descriptor_length</b>	8	1	uimsbf
<b>component_name_string()</b>	var		
}			

**descriptor\_tag** — This 8-bit unsigned integer shall have the value 0xA3, identifying this descriptor as component\_name\_descriptor.

**descriptor\_length** — This 8-bit unsigned integer specifies the length (in bytes) immediately following this field up to the end of this descriptor.

**component\_name\_string()** — The name string in the format of a Multiple String Structure (see Section 7.2).

### 6.12 Daylight Savings Time Descriptor

This descriptor is defined for optional carriage in the System Time Table section (and in no other type of table). Hosts may use the data in the descriptor if present. If not present, *no indication is being provided as to whether daylight savings time is in effect or not*. In other words, the Host shall not infer that the lack of a descriptor means that daylight savings time is not currently in effect.

A description of the use of the `daylight_savings_time_descriptor()` is provided in Annex E. The syntax is shown in the following Table.

**Table 6.10 Daylight Savings Time Descriptor format**

Syntax	Bits	Bytes	Format
<code>daylight_savings_time_descriptor() {</code>			
<b>descriptor_tag</b>	8	1	uimbsbf value 0x96
<b>descriptor_length</b>	8	1	uimbsbf
<b>DS_status</b>	1	1	bslbf
<b>reserved</b>	2		'11'
<b>DS_day_of_month</b>	5		uimbsbf
<b>DS_hour</b>	8	8	uimbsbf
<code>}</code>			

**descriptor\_tag** — This 8-bit unsigned integer shall have the value 0x96, identifying this descriptor as `daylight_savings_time_descriptor`.

**descriptor\_length** — This 8-bit unsigned integer specifies the length (in bytes) immediately following this field up to the end of this descriptor.

**DS\_status** — This bit indicates the status of daylight savings.

    DS\_status = '0': Not in daylight savings time.

    DS\_status = '1': In daylight savings time.

**DS\_day\_of\_month** — This 5-bit unsigned integer field indicates the local day of the month on which the transition into or out of daylight savings time is to occur (1-31).

**DS\_hour** — This 8-bit unsigned integer field indicates the local hour at which the transition into or out of daylight savings time is to occur (0-18). This usually occurs at 2 a.m. in the U.S.

### 6.13 User Private Descriptors

Privately defined descriptors are those with `descriptor_tag` in the range 0xC0 through 0xFF. They may be placed at any location where descriptors may be included within the table sections described in this Service Information standard. Ownership of one or more user private

descriptors is indicated by the presence of an MPEG registration\_descriptor() preceding the descriptor(s).

## 7 TEXT STRING CODING

This section describes the format of text strings in this Service Information standard. Two different formats are used in this document. Text strings in the Network Text Table uses a format called Multilingual Text String (MTS), consisting of one or more mode-length-segment blocks. The MTS format is described in Section 7.1. All other tables and descriptors use a data structure called Multiple String Structure, described in Section 7.2. The following tables summarize these rules.

**Table 7.1 Text String Coding Format in Tables**

Table ID Value (hex)	Table	Coding	Ref.
0xC3	Network Text Table (NTT)	MTS	Sec. 7.1
0xCA	Rating Region Table (RRT)	MSS	Sec. 7.2
0xD6	Aggregate Event Information Table (AEIT)	MSS	Sec. 7.2
0xD7	Aggregate Extended Text Table (AETT)	MSS	Sec. 7.2

**Table 7.2 Text String Coding Format in Descriptors**

Descriptor Tag Value (hex)	Descriptor	Coding	Ref.
0x87	Content advisory descriptor	MSS	Sec. 7.2
0xA0	Extended channel name descriptor	MSS	Sec. 7.2
0xA3	Component name descriptor	MSS	Sec. 7.2

### 7.1 Multilingual Text String (MTS) Format

The format of Multilingual Text Strings adheres to the following structure. Items in square brackets may be repeated one or more times:

<mode><length><segment> [ <mode><length><segment> ]

A `string_length` field always precedes the one or more instances of `mode`, `length`, `segment`. This field is described in each instance where multilingual text is used, and may be either 8- or 16-bits in length, as appropriate. The value of `string_length` represents the sum total of all `mode`, `length`, `segment` blocks comprising the multilingual text string to follow, and serves to indicate the end of the text string structure.

The multilingual text data structure is designed to accommodate the need to represent a text string composed of characters from a variety of alphabets, as well as ideographic characters. Whereas characters could be represented using 16- or 32-bit character codes (as does Unicode [ISO/IEC 10646-1]), that form is inefficient and wasteful of transmission bandwidth for strings composed primarily of alphabetic rather than ideographic characters. To accommodate the need to handle Chinese, Japanese, and Korean, modes are defined that allow 16-bit (double byte) character representations in standard formats.

References below to *ISO/IEC 10646-1* (Unicode) shall be to the Basic Multilingual Plane (BMP) within that standard.

**mode** — An 8-bit value representing the text mode to be used to interpret characters in the segment to follow. See Table 7.3 for definition. Mode bytes in the range zero through 0x3E select Unicode character code pages. Mode byte value 0x3F selects 16-bit Unicode character coding. Mode bytes in the range 0x40 through 0xFF represent selection of a format effector function such as *underline ON* or *new line*. If **mode** is in the range 0x40 to 0x9F, then the **length/segment** portion is omitted. Format effector codes in the range 0x40 through 0x9F involve no associated parametric data; hence the omission of the **length/segment** portion. Format effector codes in the range 0xA0 through 0xFF include one or more parameters specific to the particular format effector function.

**length** — An 8-bit unsigned integer number representing the number of bytes in the segment to follow in this block.

**segment** — An array of bytes representing a character string formatted according to the mode byte.

**Table 7.3 Mode Byte Encoding**

Mode Byte	Meaning	Language(s) or Script
0x00	Select ISO/IEC 10646-1 Page 0x00	ASCII, ISO Latin-1 (Roman)
0x01	Select ISO/IEC 10646-1 Page 0x01	European Latin (many) <sup>9</sup>
0x02	Select ISO/IEC 10646-1 Page 0x02	Standard Phonetic
0x03	Select ISO/IEC 10646-1 Page 0x03	Greek
0x04	Select ISO/IEC 10646-1 Page 0x04	Russian, Slavic
0x05	Select ISO/IEC 10646-1 Page 0x05	Armenian, Hebrew

}			
} else if (mode >= 0xA0) {			
<b>format_effector_param_length</b>	8	((1))	uimsbf
for (i=0; i<(format_effector_param_length); i++) {			
<b>format_effector_data</b>	8	((((1))))	
}			
}			
}			

### 7.1.1 Mode Byte Definition

The mode byte is used either to select an *ISO/IEC 10646-1* code page from the BMP (exact mapping, or in the case of page zero, an extended mapping as defined herein), or to indicate that the text segment is coded in one of a number of standard double-byte formats. Table 6.1 shows the encoding of the mode byte. Values in the zero to 0x33 range select ISO/IEC 10646-1 code pages.

Value 0x3F selects double-byte forms used with non-alphabetic script systems, where the segment consists of a sequence of 16-bit character codes according to the *ISO/IEC 10646-1* standard. Byte ordering is high-order byte first (Motorola 680xx style), also known as *big-endian*.

### 7.1.2 Format Effectors

Mode bytes in the 0x40 to 0xFF range are defined as format effectors. Table 7.5 defines the encoding for currently defined single-byte values. Format effectors in the range 0x40 through 0x9F are self-contained, and do not have a length or data field following them. Format effectors in the range 0xA0 through 0xFF include a multi-byte parameter field. No multi-byte format effectors are currently defined.

#### 7.1.2.1 Line Justification

Values 0x80, 0x81, and 0x82 signify the end of a line of displayed text. Value 0x80 indicates that the text is displayed left justified within an enclosing rectangular region (defined outside the scope of the text string). Value 0x81 indicates that the text is displayed right justified. Value 0x82 indicates that the text is centered on the line. The dimensions and location on the screen of the box into which text is placed is defined outside the scope of the text string itself.

**Table 7.5 Format Effector Function Codes**

Mode Byte	Meaning
0x40-0x7F	Reserved
0x80	new line, left justify
0x81	new line, right justify
0x82	new line, center
0x83	italics ON
0x84	italics OFF
0x85	underline ON
0x86	underline OFF
0x87	bold ON
0x88	bold OFF
0x89-0x9F	Reserved

### 7.1.2.2 Italics, Underline, Bold Attributes

These format effectors toggle *italics*, underline, and **bold** display attributes. The italics, underline, and bold format effectors indicate the start or end of the associated formatting within a text string. Formatting extends through new lines. For example, to display three lines of bold text, only one instance of the *bold ON* format effector is required.

### 7.1.2.3 Processing of Unknown or Unsupported Format Effectors

Hosts must discard format effectors that are unknown, or known not to be supported within a specific Host model. If a parameter value carries an undefined value, that format effector is expected to be discarded.

### 7.1.3 Default Attributes

Upon entry to a multilingual text string, all mode toggles (bold, underline, italics) shall be assumed “OFF”.

### 7.1.4 Mode Zero

*ISO/IEC 10646-1* page zero (U+0000 through U+00FF) includes ASCII in the lower half (U+0000 through U+007F), and Latin characters from ISO 8859-1, *Latin-1*, in U+0090 through U+00FF. This set of characters covers Danish, Dutch, Faroese, Finnish, French, German, Icelandic, Irish, Italian, Norwegian, Portuguese, Spanish and Swedish. Many other languages can be written with this set of letters, including Hawaiian, Indonesian/Malay, and Swahili.

Table 7.6 shows encodings of page zero characters in the range 0x80 through 0x9F (these are undefined within *ISO/IEC 10646-1*).

**Table 7.6 Encodings of Columns 8 and 9 of Mode Zero Latin Character Set**

D	<RESERVED>	U+2191 — <UP ARROW>
E	<RESERVED>	U+2192 — <RIGHT ARROW>
F	<RESERVED>	U+2193 — <DOWN ARROW>

### 7.1.5 Supported Characters

Support for specific characters and languages depends upon the specific model of Standard-compatible Host. Not all Hosts support all defined character sets or character codes. Use of multilingual text must be predicated on the knowledge of limitations in character rendering inherent in different Host models for which text is available.

## 7.2 Multiple String Structure (MSS)

The Multiple String Structure is a general data structure used specifically for text strings. Text strings appear as event titles, long channel names, the ETT messages, and RRT text items. The bit stream syntax for the Multiple String Structure is shown in Table 7.7.

**number\_strings** — This 8-bit unsigned integer field identifies the number of strings in the following data.

**ISO\_639\_language\_code** — This 3-byte (24 bits) field, in conformance with ISO 639.2/B, specifies the language used for the  $i^{\text{th}}$  string.

**number\_segments** — This 8-bit unsigned integer field identifies the number of segments in the following data. A specific mode is assigned for each segment.

**Table 7.7 Multiple String Structure**

Syntax	Bits	Format
multiple_string_structure () {		
<b>number_strings</b>	8	uimsbf
for (i= 0;i< number_strings;i++) {		
<b>ISO_639_language_code</b>	8*3	uimsbf
<b>number_segments</b>	8	uimsbf
for (j=0;j<number_segments;j++) {		
<b>compression_type</b>	8	uimsbf
<b>mode</b>	8	uimsbf
<b>number_bytes</b>	8	uimsbf
for (k= 0;k<number_bytes;k++)		
<b>compressed_string_byte [k]</b>	8	bslbf
}		
}		
}		

**compression\_type** — This 8-bit field identifies the compression type for the j<sup>th</sup> segment. Allowed values for this field are shown in Table 7.8.

**Table 7.8 Compression Types**

compression_type	compression method
0x00	No compression
0x01	Huffman coding using standard encode/decode tables defined in Table C.4 and C.5 in Annex C of Ref. [5].
0x02	Huffman coding using standard encode/decode tables defined in Table C.6 and C.7 in Annex C of Ref. [5].
0x03 to 0xAF	Reserved
0xB0 to 0xFF	User private

**mode** — An 8-bit value representing the text mode to be used to interpret characters in the segment to follow. See Table 7.9 for definition. Mode values in the range zero through 0x3E select 8-bit Unicode™ character code pages. Mode value 0x3F selects 16-bit Unicode™ character coding. Mode values 0x40 through 0xDF are reserved for future use by ATSC. Mode values 0xE0 through 0xFE are user private. Mode value 0xFF indicates the text mode is not applicable. Hosts shall ignore string bytes associated with unknown or unsupported mode values.

**number\_bytes** — This 8-bit unsigned integer field identifies the number of bytes that follows.

**compressed\_string\_byte[k]** — The k<sup>th</sup> byte of the j<sup>th</sup> segment.

**Table 7.9 Modes**

<b>Mode</b>	<b>Meaning</b>	<b>Language(s) or Script</b>
0x00	Select ISO/IEC 10646-1 Page 0x00	ASCII, ISO Latin-1 (Roman) <sup>13</sup>

0xFF	Not applicable	

<sup>13</sup> The languages supported by ASCII plus the Latin-1 supplement include Danish, Dutch, English, Faroese, Finnish, Flemish, German, Icelandic, Irish, Italian, Norwegian, Portuguese, Spanish and Swedish. Many other languages can be written with this set of characters, including Hawaiian, Indonesian, and Swahili.

<sup>14</sup> When combined with page zero (ASCII and ISO Latin-1), covers Afrikaans, Breton, Basque, Catalan, Croatian, Czech, Esperanto, Estonian, French, Frisian, Greenlandic, Hungarian, Latin, Latvian, Lithuanian, Maltese, Polish, Provençal, Rhaeto-Romanic, Romanian, Romany, Sami, Slovak, Slovenian, Sorbian, Turkish, Welsh, and many others.

<sup>15</sup> Also Persian, Urdu, Pashto, Sindhi, and Kurdish.

<sup>16</sup> Devanagari script is used for writing Sanskrit and Hindi, as well as other languages of northern India (such as Marathi) and of Nepal (Nepali). In addition, at least two dozen other Indian languages use Devanagari script.

**ANNEX A****OPERATIONAL PROFILES FOR CABLE  
SERVICE INFORMATION DELIVERY****(Normative)****A.1 Operational Profiles**

This document specifies Service Information tables that are required for delivery via an out-of-band channel on cable. Six profiles are described with required and optional data specified for out-of-band transport via cable. Adherence to these profile specifications is necessary for compliance with SCTE standard transport streams.

**A.1.1 Profile 1 – Baseline**

This Baseline Profile reflects a practice in cable where the Short-Form Virtual Channel Table, the Modulation Mode Subtable and the Carrier Definition Subtable are used for channel navigation.

**A.1.2 Profile 2 – Revision Detection**

Profile 2 uses the same channel navigation mechanism as Profile 1 while adding a detection mechanism that facilitates revision handling of tables. The revision detection mechanism is applicable to the Network Information Table, Network Text Table, and S-VCT that are also used in Profile 1.

**A.1.3 Profile 3 – Parental Advisory**

Profile 3 uses Profile 2 as the base and adds support for the Rating Region Table in order to be compliant with the FCC-mandated V-chip content advisory scheme. Since for the U.S. and its possessions, EIA-766 [14] defines the contents of version 0 RRT, use of RRT is more applicable to outside of North America. The channel navigation mechanism is the same as in Profile 1.

**A.1.4 Profile 4 – Standard Electronic Program Guide Data**

Profile 4 uses Profile 3 as the base and further defines a standard format for delivery of Electronic Program Guide data by using the Aggregate Event Information Table and the Aggregate Extended Text Table. The Master Guide Table shall be supported to manage the AEITs, AETTs and other applicable tables from Profile 3. The same mechanism as in Profile 1 is used for channel navigation.

#### **A.1.5 Profile 5 – Combination**

Support for channel navigation based on L-VCT and MGT is added. Backward compatibility with systems operating within profiles 1 to 4 is maintained. Using profile 5, a cable operator could have a mixture of devices requiring the S-VCT, NIT and NTT tables as well as ones requiring the long-form tables: i.e., L-VCT, MGT.

When using profile 5, both the S-VCT and the L-VCT shall be present, and each shall describe all available services.

#### **A.1.6 Profile 6 – PSIP Only**

Profile 6 is based solely on long-form tables and is an extension of the terrestrial broadcasting mechanism. Channel navigation is based on the Long-form Virtual Channel Table. The AEIT and the optional AETT streams are used to provide EPG data.

### ***A.2 Profile Definition Tables***

In order to conform to this SCTE Service Information standard, a cable operator shall send a collection of tables that corresponds to one or more of the defined operational profiles defined in Table A.1 and Table A.2.

**Table A.1 Usage of Table Sections in Various Profiles**

		<b>Profile 1</b>	<b>Profile 2</b>	<b>Profile 3</b>	<b>Profile 4</b>	<b>Profile 5</b>	<b>Profile 6</b>
<b>Table Section</b>	table ID	Baseline	Revision Detection	Parental Advisory	Standard EPG Data	Combination	PSIP only (a)
<b>Network Information Table</b>	0xC2						
<b>Carrier Definition Subtable</b>		M	M	M	M	M	-
<b>Modulation Mode Subtable</b>		M	M	M	M	M	-
<b>Network Text Table</b>	0xC3						
<b>Source Name Subtable</b>		O	O	O	M	M	-
<b>Short-form Virtual Channel Table</b>	0xC4						
<b>Virtual Channel Map</b>		M	M	M	M	M	-
<b>Defined Channels Map</b>		M	M	M	M	M	-
<b>Inverse Channel Map</b>		O	O	O	O	O	-
<b>System Time Table</b>	0xC5	M	M	M	M	M	M

**Legend:**

- M Mandatory (shall be present)
- O Optional (may or may not be present)
- Not applicable (shall not be present)

**Notes:**

- a. Exception: System Time Table (table ID 0xC5 is used here instead of table ID 0xCD defined in PSIP) and other modifications.
- b. The content\_advisory\_descriptor() shall be present in the AEIT and PMT for a given program when Content Advisory data is available for that program. It is not required for programs for which Content Advisory data is not available.

**A.3 Operational Considerations for the use of profiles (Informative)**

1. If devices deployed in a particular cable system require the S-VCT in Profiles 1-5 for navigation, cable operator's use of P6 will cause operational problems.
2. If devices in use require L-VCT for navigation, cable operator's use of Profiles 1-4 will cause operational problems.
3. To provide EPG data, cable-ready devices operating on a cable system conforming to Profiles 1, 2 or 3 must use alternative protocols and methods which are beyond the scope of this specification.

## ANNEX B

### IMPLEMENTATION RECOMMENDATIONS

#### (Informative)

##### ***B.1 Implications for Retail Digital Cable-Ready Devices***

Given that a cable operator could choose to deliver SI tables according to any of the profiles defined in Annex A on any given hub, digital cable-ready devices offered for retail sale should be able to accept a Short-form Virtual Channel Table for basic navigation if the Long-form Virtual Channel is not provided. It should also accept the Long-form Virtual Channel Table if the Short-form table is not provided.

##### ***B.2 Channel Number Handling***

Host devices are expected to support navigation based on virtual channel records associated with two-part channel numbers. If an S-VCT virtual channel record includes a `two_part_channel_number_descriptor()`, the Host is expected to use it, and to disregard the 12-bit `virtual_channel_number` field in the same `virtual_channel()` record.

If a `two_part_channel_number_descriptor()` is not present in the record-level descriptors loop of a particular S-VCT virtual channel record, the Host is expected to use the `virtual_channel_number` field in the `virtual_channel()` record, (see Table 5.17) as the channel number reference.

Both numbering schemes may co-exist in a channel map, but each individual channel must be considered labeled with either a one-part or a two-part number.

##### ***B.3 Processing of Dynamic Changes to Service Information***

The Host is expected to monitor SI data on a continuous basis, and react to changes dynamically. For example, an update to an S-VCT or L-VCT may indicate that the definition of the currently acquired virtual channel has changed. The change could involve, for example, association of the channel with a different MPEG-2 `program_number` within a Transport Stream on a different carrier frequency. In response to such a change, the Host is expected to tune to and acquire the service as redefined.

For some types of changes, the Host is not expected to respond in a visible way. For example, the name of the current event may change, but the new name would be visible as the response to a regular user action to show the event name on-screen or in a program guide display.

##### ***B.4 AEITs May Include Event Information for Inaccessible Channels***

In the out-of-band system, depending on the data delivery methods employed by the cable headend and POD module, there may be occasions where AEITs are broadcast for which some Hosts do not have corresponding virtual channel assignments. In these cases, the Host is

expected to discard portions of the AEITs corresponding to `source_ID` values not present in the Virtual Channel Table (short- or long-form).

For example, the AEIT may include data describing the program schedule for a service identified with `source_ID` value 0x0123. Let's say the Virtual Channel Table does not include a channel associated with `source_ID` 0x0123. When constructing a program guide display, the channel name, number and physical location associated with events tied to `source_ID` 0x0123 will not be available. Therefore, the events described in the AEIT data for this channel are inaccessible, and the AEIT records for this `source_ID` should be discarded.

### ***B.5 Splice Flag Processing***

The S-VCT includes a flag called `splice`. Hosts supporting application of virtual channel changes tied to video splice point timing are expected to execute the change after two seconds following the `activation_time`, in the absence of a video splice point prior to that time.

Support of the splice timing function is optional in Hosts. A Host not supporting the splice timing feature is expected to apply the data delivered in the `VCM_structure()` at the indicated activation time (i.e. the `splice` flag may be simply disregarded).

## ANNEX C

### SERVICE INFORMATION OVERVIEW AND GUIDE

#### (Informative)

##### C.1 Table Hierarchy

Figure C.1 through Figure C.5 describe the relationships between SI tables for profiles 1 through 6 in a simplified form. A mandatory table is shown in solid box. An optional table is shown in dotted box. An italicized name indicates a sub-table or a map carried within the table.

The Short-form Virtual Channel Table section (*table\_ID* 0xC4) or the Long-form Virtual Channel Table (*table\_ID* 0xC9) provide navigation data on the out-of-band path. If MGT is provided, it references all tables present in Service Information (except the System Time Table).

The Master Guide Table provides general information about all of the other tables including the S-VCT, L-VCT, RRT, AEIT, and AETT. It defines table sizes necessary for memory allocation during decoding; it defines version numbers to identify those tables that need to be updated; and it gives the packet identifier (PID) values associated with instances of AEITs and AETTs.

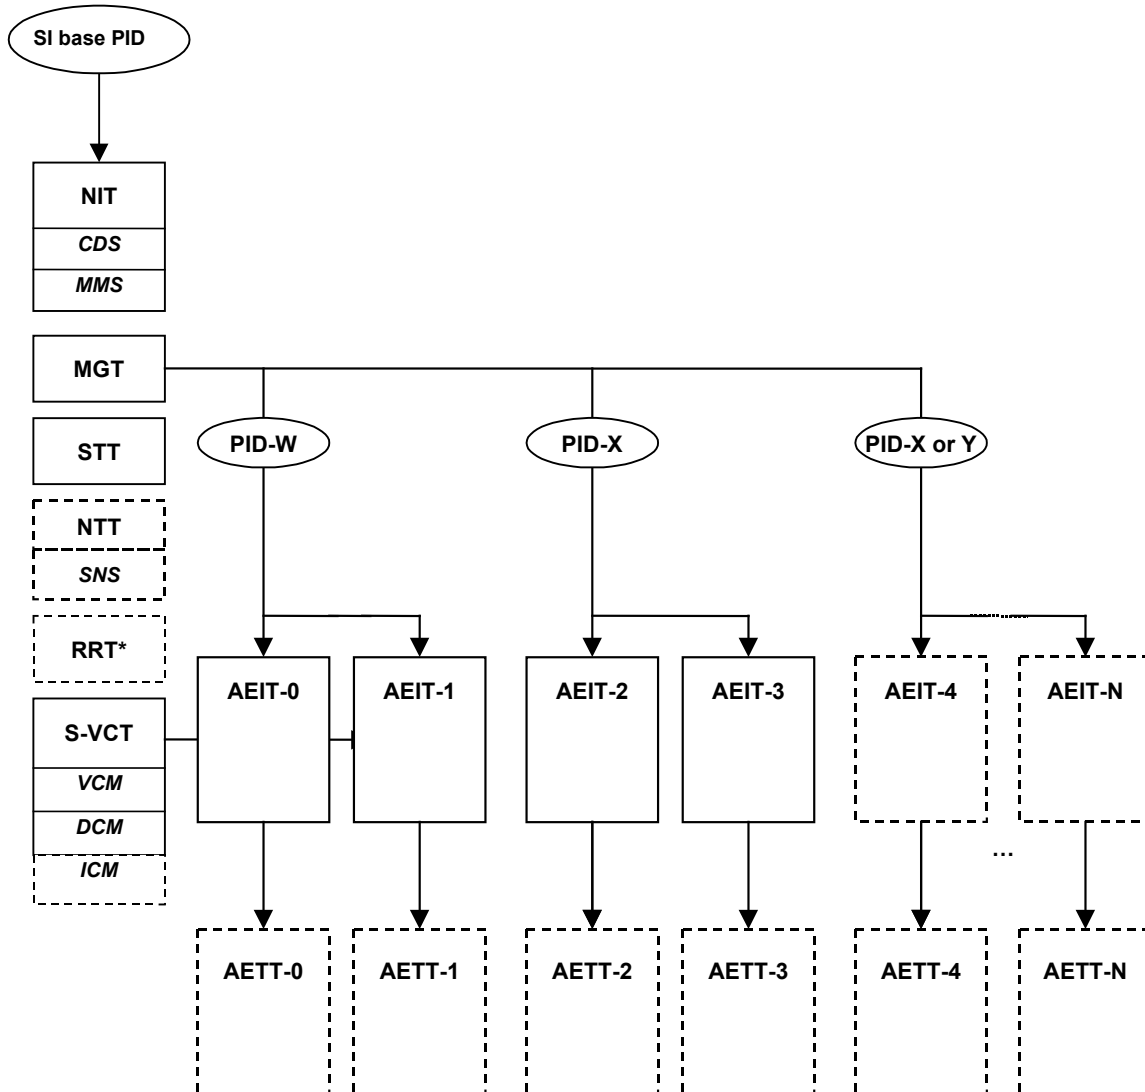

Figure C.1 Hierarchy of Table Sections -- Profiles 1 and 2

In Profile 3 and higher, the Rating Region Table must be included, with one exception, to describe rating regions in use. The exception is that delivery of version 0 of the RRT for region 0x01 (US and possessions), need not be sent because this table is standardized in EIA-766 [14]. Furthermore, for Profile 3, the MGT need not be sent if no RRT is sent.

**Figure C.2 Hierarchy of Table Sections -- Profile 3**

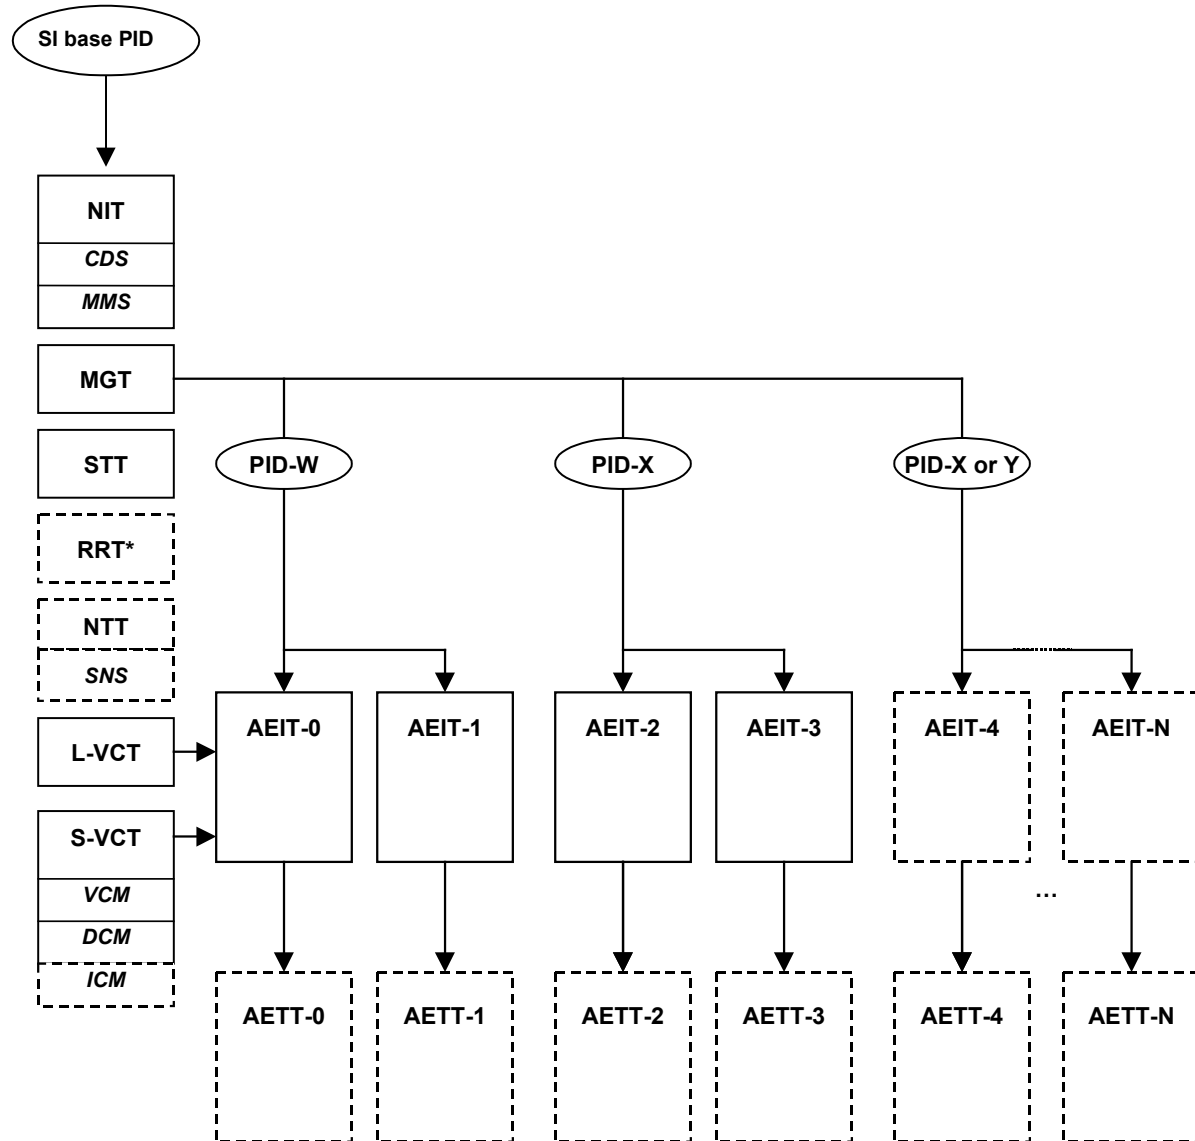

**Figure C.3 Hierarchy of Table Sections -- Profile 4**

Aggregate Event Information Tables are included in the out-of-band data in Profiles 4-6. Each AEIT instance describes the events or TV programs associated with a particular three-hour time slot. In the AEIT table structure, program schedule and title data for all virtual channels is aggregated together.

Each AEIT instance is valid for a time interval of three hours. As shown in Figure C.3, at minimum, AEIT-0 through AEIT-3 must be sent. Therefore, when Profiles 4-6 are used, current program information and information covering nine to twelve hours of future programming will be available to the Host.

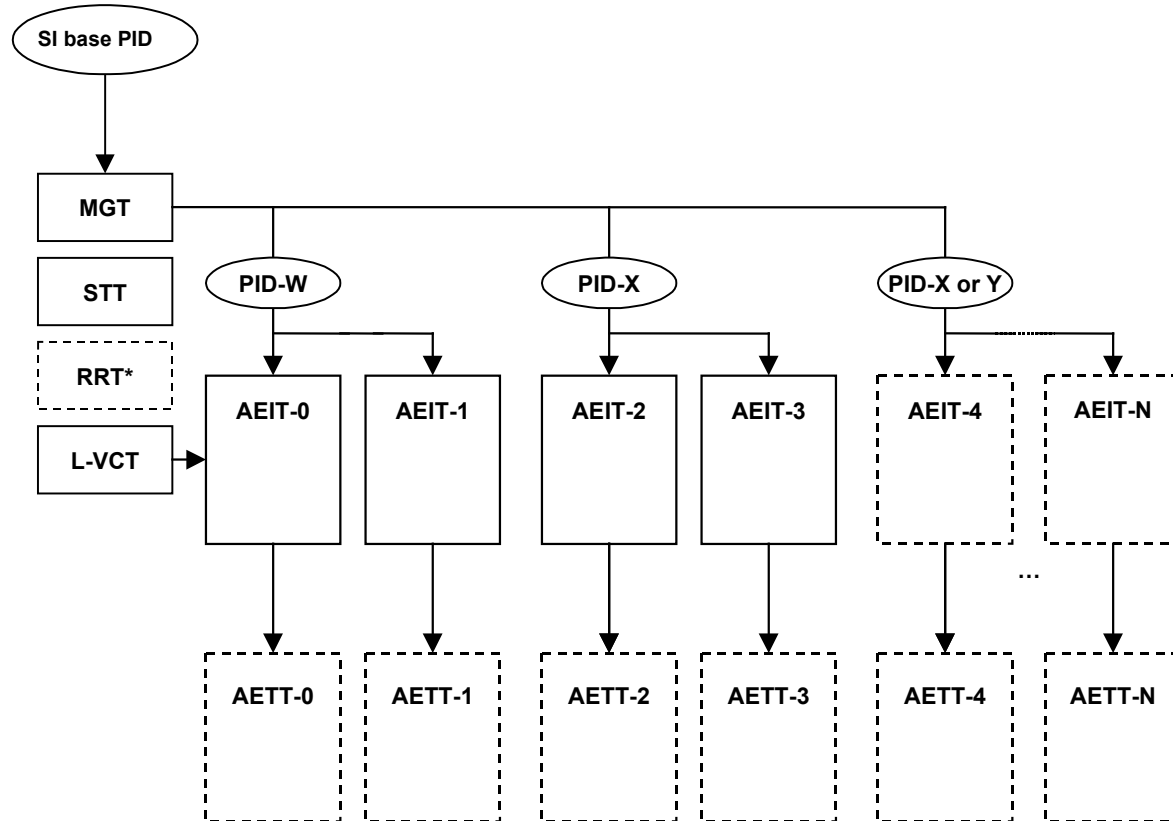

Up to 256 AEITs may be transmitted; over 30 days of future programming may therefore be described. For the fourth timeslot and beyond (AEIT-4 through AEIT-N), the tables may be associated with the same or different PID values.

**Figure C.4 Hierarchy of Table Sections -- Profile 5**

The start time for any AEIT is constrained to be one of the following UTC times: 00:00 (midnight), 03:00, 06:00, 09:00, 12:00 (noon), 15:00, 18:00, and 21:00. Imposing constraints on the start times as well as the interval duration simplifies re-multiplexing. During re-multiplexing, AEIT tables coming from several distinct Transport Streams may end up grouped together or *vice versa*. If no constraints were imposed, re-multiplexing equipment would have to parse AEIT by content in real time, which is a difficult task.

However, it is also possible to regenerate one or several AEIT at any time for correcting and/or updating the content (e.g. in cases where “to be assigned” events become known). Regeneration of an AEIT may be flagged by updating version fields in the MGT. A new AEIT may also be associated with a PID value not in current use. The MGT may be updated to show this new PID value association.

**Figure C.5 Hierarchy of Table Sections -- Profile 6**

In Profiles 4-6, there can be several Aggregate Extended Text Tables, each of them having its associated PID defined in the MGT. As its name indicates, the purpose of an Aggregate Extended Text Table is to carry textual data. For example, for an event such as a movie listed in the AEIT, the typical data is a short paragraph that describes the movie itself. Each Aggregate Event Information Table can have one associated AETT. Each AETT instance includes all the text associated with events starting within a particular timeslot. Aggregate Extended Text Tables are optional in Profiles 4-6.

### C.2 *SI\_base PID*

Data associated with the *SI\_base* PID defines information of system-wide applicability such as frequency plans, channel maps, and channel names. The *SI\_base* PID value is 0x1FFC. The types of table sections that may be included in the Network Stream include:

- ◆ Network Information Table, carrying the
  - ◆ Carrier Definition Subtable
  - ◆ Modulation Mode Subtable
- ◆ Network Text Table, carrying the Source Name Subtable
- ◆ Short-form Virtual Channel Table, carrying the
  - ◆ Virtual Channel Map

- ◆ Defined Channels Map
- ◆ Inverse Channels Map
- ◆ Long-form Virtual Channel Table
- ◆ Master Guide Table
- ◆ Rating Region Table
- ◆ System Time Table

### ***Carrier Definition Subtable***

The Carrier Definition Subtable provides a foundation for the definition of frequency plans by defining a set of carrier frequencies appropriate to a particular transmission medium. The CDS is stored in the Host as an array of as many as 255 CDS records, each consisting of:

- Carrier frequency, 15 bits, in units of 10 or 125 kHz

### ***Modulation Mode Subtable***

The Modulation Mode Subtable provides a foundation for quick acquisition of digitally modulated waveforms. A separate MMS shall be transmitted in Network data for each transmission medium supported by that network. An MMS is stored in the Host as an array of up to 255 MMS records, each consisting of:

- Modulation format: analog NTSC or QAM
- Transmission system: ITU-T (North America) or ATSC
- Symbol rate, in units of 1 Hz
- Inner coding mode, expressed as either “none” or an integer ratio such as 1/2 or 3/4
- For QAM modulation, the number of levels

Each MMS contains entries for each modulation mode currently in use by any digital waveform, plus entries for any modes anticipated to be used. As with the CDS, changes to the table are rare.

Parameters defined within the MMS are not specifically manipulated by Hosts compliant with the SI protocol, but are referenced by the Host when attempting to acquire a digitally encoded and modulated waveform.

### ***Short-form Virtual Channel Table and Virtual Channel Record***

The Short-form Virtual Channel Table is a hierarchical data structure that may carry within it the Virtual Channel Map and Virtual Channel record, for support of up to 4096 channel definition records. Each virtual channel is associated with a 16-bit reference ID number called the `source_ID`. Each record in the VCM consists of:

- The MPEG program number, associating the virtual channel record with a program defined in the Program Association Table and TS Program Map Table

- For virtual channels associated with programs carried in a program guide, the `source_ID`, a number that may be used to link the virtual channel to entries in the Electronic Program Guide (EPG) database
- For virtual channels used as access paths to application code or data (such as EPG), the *application ID*<sup>17</sup>

### ***Source ID***

Source ID is a 16-bit number associated with each program source, defined in such a way that every programming source offered anywhere in the system described in this Service Information standard is uniquely identified. For example, HBO/W has a different assigned source ID than HBO/E, and both are different from HBO-2 or HBO-3. Uniqueness is necessary to maintain correct linkages between an EPG database and virtual channel tables. See below for a discussion of the relationship between `source_ID`, virtual channels, and an EPG database.

### ***Source Names and Source Name Subtable***

The Source Name is a variable length multilingual text string associating a source ID with a textual name. The Source Name Subtable is delivered within the Network Text Table section.

Source name information is delivered in a table format separate from the table containing other information comprising the virtual channel table. Name information is not strictly necessary for channel acquisition, and (depending on the memory management scheme employed in the Host) may not always be available from memory at acquisition time. Source name information may be refreshed often, and can be available within several seconds of acquisition.

An EPG database may define textual reference names associated with given program sources (referenced by source ID). Such a database may be used to derive virtual channel names in some applications, though in an EPG database the name is generally abbreviated due to display considerations.

Name data is, unlike the regular VCT data, language tagged, so that multilingual source names may be defined. Transmission format for multilingual text is defined to include references to multiple phonetic and ideographic character sets.

### ***Defined Channels Map and Inverse Channels Map***

For a given Standard-compliant channel, DCM data consist of a series of bytes that, taken as a whole, specify which channels in the map are defined, and which are not.

Each Virtual Channel Table has associated with it a table listing `source_IDS` and their associated virtual channel numbers. The `source_ID` values are sorted by value from the lowest to

---

<sup>17</sup> Source ID and application ID need never be defined in the same virtual channel record, therefore they share a common 16-bit field in the stored map. Channels are defined as for “application access” or not; if they are application access, the field defines the application ID, if not, it defines the source ID.

the highest in the table, to facilitate (using a binary search) lookup of a virtual channel given a source ID.

### ***Master Guide Table***

Use of the MGT is optional in certain profiles. Table C.1 shows a typical Master Guide Table indicating, in this case, the existence in the Transport Stream of a Long-form Virtual Channel Table, the Rating Region Table, four Aggregate Event Information Tables, and two Aggregate Extended Text Tables describing the first six hours' events.

The first entry of the MGT describes the version number and size of the Long-form Virtual Channel Table. The second entry corresponds to an instance of the Rating Region Table for region 6. If some region's policy makers decided to use more than one instance of an RRT, the MGT would list each PID, version number, and size.

The next entries in the MGT correspond to the four AEITs that must be supplied in the Transport Stream for profiles 4-6. After the AEITs, the MGT references four Aggregate Extended Text Tables. The PID values for AEIT-0 and AEIT-1 are both 0x1DD2. MGT\_tag values 56 and 57 are used for these. For AEIT-2 AEIT-3, PID 0x1DD3 is used. The last four references are to Aggregate ETTs.

Note that AETT-n shares a common PID value with AEIT-n for every value of n. AEIT-0 and AETT-0 are associated with PID 0x1DD2, as are AEIT-1 and AETT-1. AEIT-2 and AETT-2 are associated with PID 0x1DD3, etc.

Descriptors can be added for each entry as well as for the entire MGT. By using descriptors, future improvements can be incorporated without modifying the basic structure of the MGT. The MGT is like a flag table that continuously informs the Host about the status of all the other tables (except the System Time which has an independent function). The MGT is continuously monitored at the Host to prepare and anticipate changes in the channel/event structure. When tables are changed at the broadcast side and the PID association is unchanged, their version numbers are incremented and the new numbers are listed in the MGT. Another method that can be used to change tables is to associate the updated tables with different PID values, and then update the MGT to reference the new PID values. Based on the MGT version or PID updates and on the memory requirements, the Host can reload the newly defined tables for proper operation.

**Table C.1 Example Master Guide Table content**

table_type	PID	version_number	table size (bytes)
LVCT	0x1FFC	4	5922
RRT – region 6	0x1FFC	0	1020
AEIT-0 – MGT_tag = 56	0x1DD2	6	29,250
AEIT-1 – MGT_tag = 57	0x1DD2	4	28,440
AEIT-2 – MGT_tag = 58	0x1DD3	10	25,704
AEIT-3 – MGT_tag = 59	0x1DD3	2	27,606
AETT-0 – MGT_tag = 56	0x1DD2	2	24,004
AETT-1 – MGT_tag = 57	0x1DD2	7	25,922
AETT-2 – MGT_tag = 58	0x1DD3	8	27,711
AETT-3 – MGT_tag = 59	0x1DD3	0	19,945

Table C.2 is an example MGT that may be sent after the instance in Table C.1 has expired due to the passage of time. In this example, three hours have passed, and the time slot covered in the old AEIT-0 is in the past. The AEIT with MGT\_tag = 57 moves now to become AEIT-0. The AEIT with MGT\_tag = 58, the new AEIT-1, moves to PID 0x1DD2. A new AEIT is added to the mix, the AEIT with MGT\_tag = 60.

**Table C.2 Example Revised Master Guide Table content**

table_type	PID	version_number	table size (bytes)
LVCT	0x1FFC	4	5922
RRT – region 6	0x1FFC	0	1020
AEIT-0 – MGT_tag = 57	0x1DD2	4	28,440
AEIT-1 – MGT_tag = 58	0x1DD2	10	25,704
AEIT-2 – MGT_tag = 59	0x1DD3	2	27,606
AEIT-3 – MGT_tag = 60	0x1DD3	0	30,055
AETT-0 – MGT_tag = 57	0x1DD2	7	25,922
AETT-1 – MGT_tag = 58	0x1DD2	8	27,711
AETT-2 – MGT_tag = 59	0x1DD3	0	19,945
AETT-3 – MGT_tag = 60	0x1DD3	0	22,522

***L-VCT***

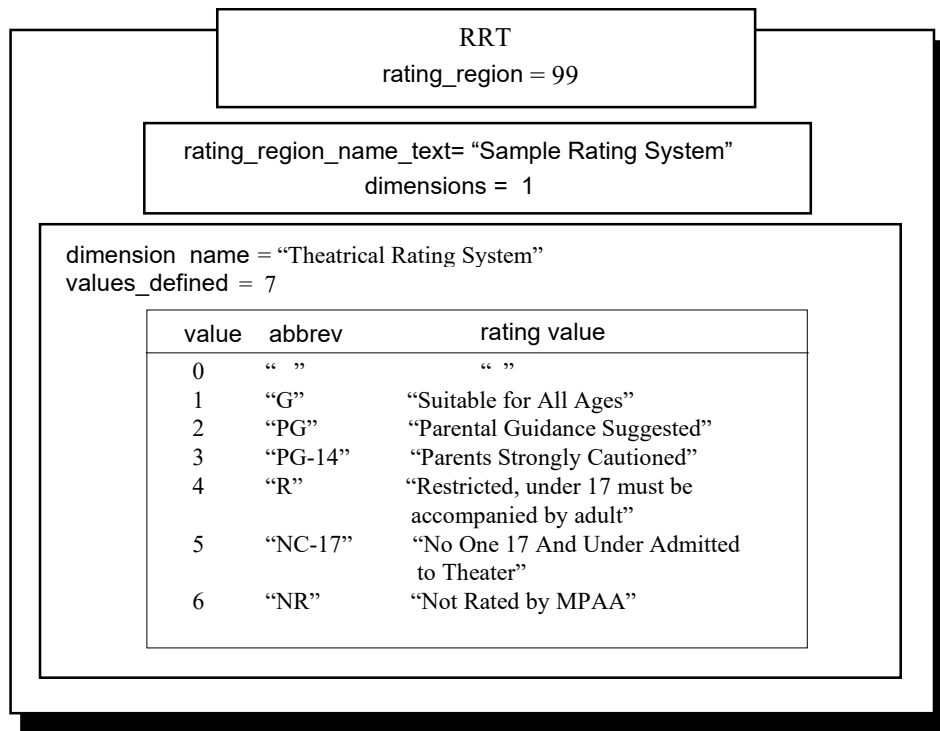

The L-VCT combines all the data pertinent to the description of a virtual channel into a single table. Use of the L-VCT instead of the S-VCT eliminates the need to send CDS, MMS, SNS, DCM, or ICM. The L-VCT follows the standard MPEG-2 long-form section syntax (section\_syntax\_indicator = 1).

**Rating Region Table**

The Rating Region Table is a fixed data structure in the sense that its content remains mostly unchanged. It defines the rating standard that is applicable for each region and/or country. The concept of table instance introduced in the previous Section is also used for the RRT. Several instances of the RRT can be constructed and carried in the Transport Stream simultaneously. Each instance is identified by a different `table_id_extension` value (which becomes the `rating_region` in the RRT syntax) and corresponds to one and only one particular region. Each instance has a different version number which is also carried in the MGT. This feature allows updating each instance separately.

Figure C.6 shows an example of one instance of an RRT, defined for rating region 99 and carrying an example rating system. Each event listed in any of the EITs may carry a content advisory descriptor. This descriptor is an index or pointer to one or more instances of the RRT.

**Figure C.6 An instance of a Rating Region Table**

**Aggregate Event Information Tables and Aggregate Extended Text Tables**

The purpose of an AEIT is to list all events for those channels that appear in the VCT for a given time window. As mentioned before, AEIT-0 describes the events for the first 3 hours and AEIT-1 for the second 3 hours. AEIT-0 and AEIT-1 share a common associated PID value as defined in the MGT. In MPEG, tables can have a multitude of instances. When different instances of a table share the same `table_id` value and PID, they are distinguished by differences in the 16-bit `table_id_extension` field.

In this SI standard for out-of-band use, each instance of AEIT-k contains a list of events for a each virtual channel. Linkage to each channel in the VCT is made via the `source_id`. For the AEIT, the `table_id_extension` field appears as `MGT_tag`.

Figure C.7 shows, for example, a program provider's instance for AEIT-0.

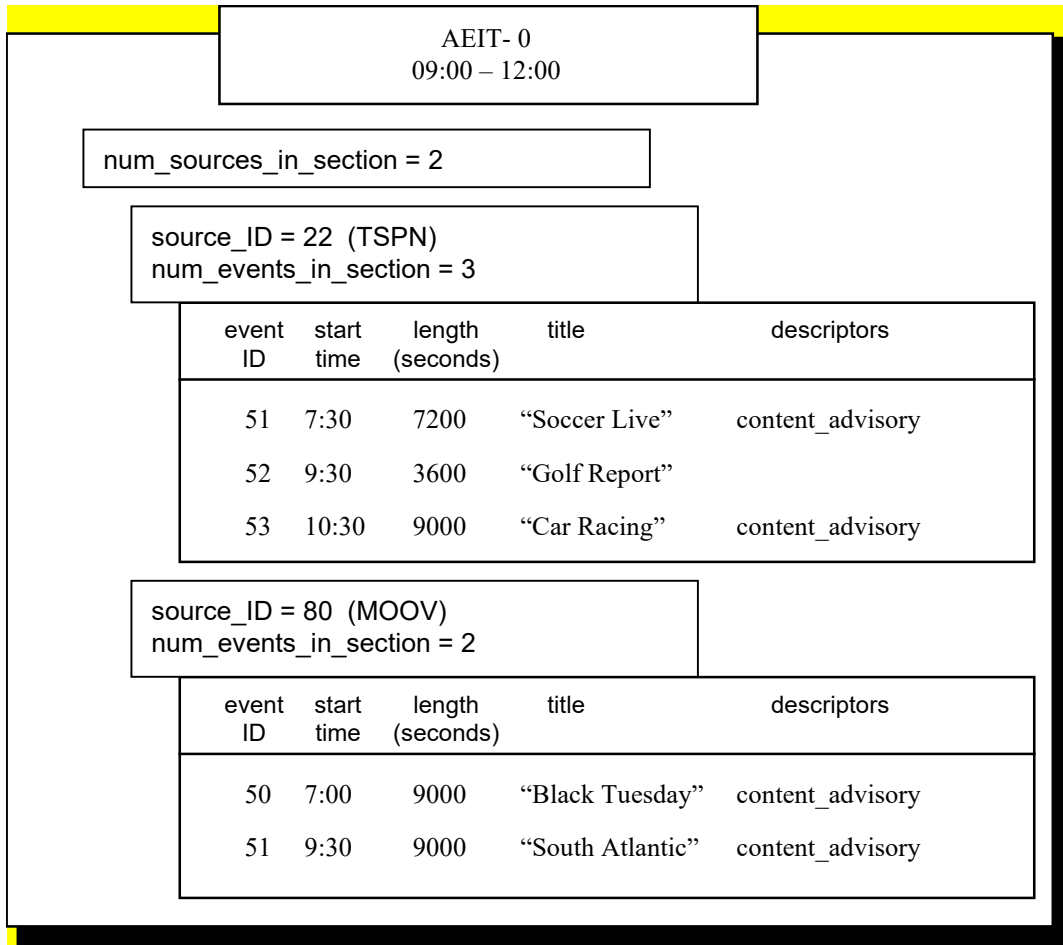

AEIT-0 is unique in that it must list all events starting within the three-hour time period it covers, as well as any events that started earlier but extend into the covered period. For all other AEITs, only those events actually starting within the three hour time period are included. The Host is expected to collect AEITs in order of their time coverage. If AEIT-4 is available to the Host but AEIT-3 is not, for example, information for events that started in the time period covered by AEIT-3 but extending into AEIT-4 will not be available for display.

Figure C.7 shows an example of a small AEIT-0, including event data for two sources, a channel called "TSPN" (`source_ID` 22) and one called "MOOV" (`source_ID` 80). For the three-hour period covered by AEIT-0, 9am to noon, three events are listed for TSPN and two for MOOV. The field `event_id` is a number used to identify each event. The `event_id` is used to link events with associated text delivered in the AETT. The assignment of an `event_ID` value must be unique within a source ID and a 3-hour interval defined by one AEIT instance. The `event_id` is followed by the `start_time` and then the `length_in_seconds`. Notice that for AEIT-0 only, events can have start times before the activation time of the table. ETMs are simply long textual descriptions. The collection of ETMs constitutes an Aggregate Extended Text Table (ETT).

An example of an ETM for the Car Racing event may be:

"Live coverage from Indianapolis. This car race has become the largest single-day sporting event in the world. Two hundred laps of full action and speed."

Several descriptors can be associated with each event. The most important is the content advisory descriptor which assigns a rating value according to one or more systems. Recall that the actual rating system definitions are tabulated within the RRT.

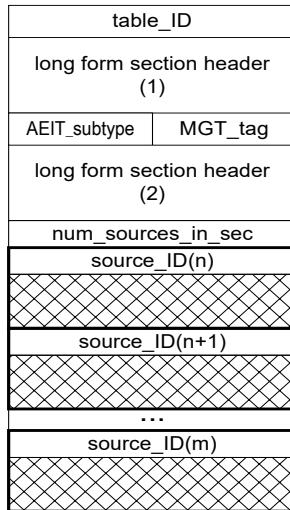

**Figure C.7 Example AEIT-0**

Figure C.8 diagrams the AEIT data structure. As shown, the AEIT includes event data for all sources listed in the VCT. In the figure, the hatched box represents one or more “event data” blocks, each comprised of the data items shown in the upper left.

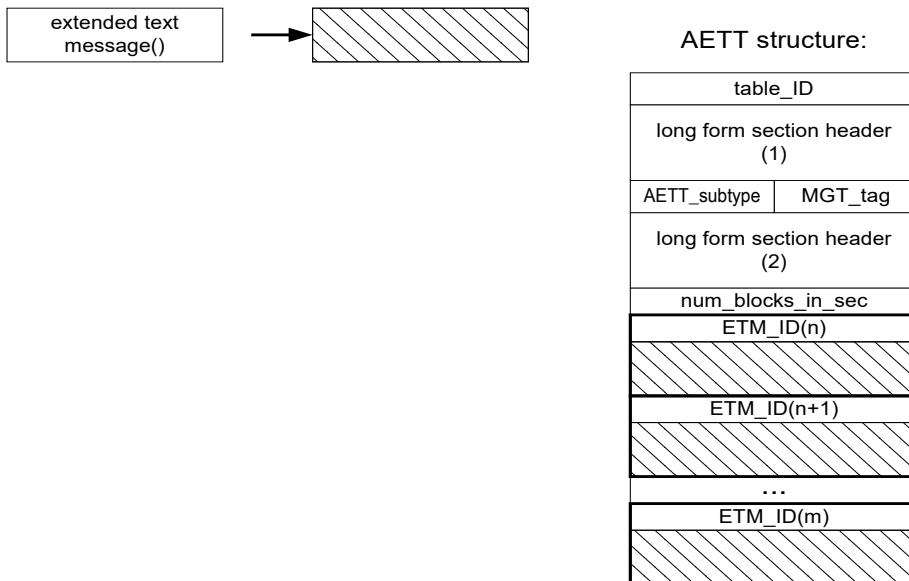

AEIT structure:

**Figure C.8 AEIT data structure**

Figure C.9 diagrams the AETT data structure. The AETT aggregates text for a given timeslot into one sectioned MPEG table.

**Figure C.9 Structure of AETT**

An AETT- $n$  instance for a given value of  $n$  (timeslot) is associated with the same PID value as AEIT- $n$ . This means that they can be collected using a single Extended Channel data flow between Host and POD.

### ***Inactive Channels***

Any channels in the L-VCT which are not currently active shall have the hidden attribute set to 1 and the hide\_guide attribute set to 0. Inactive channels in the S-VCT shall have the hidden attribute in channel\_type, and the hide\_guide flag in the channel\_properties\_descriptor() set to 0.

The following table shows expected DTV behavior for the various combinations of the hidden and hide\_guide attributes. In the table the “x” entry indicates “don’t care.” A check in the “surf” column indicates the channel is available by channel surfing and via direct channel number entry. A check in the “guide” column indicates that the channel may appear in the program guide listing.

**Table C.3 Receiver Behavior with hidden and hide\_guide attributes**

hidden	hide_guide	Receiver Behavior		
		Surf	Guide	
0	x	✓	✓	Normal channel
1	1			Special access only
1	0		✓	Inactive channel

### ***C.3 Representation of Time***

The System Time Table provides time of day information to Hosts. In this Service Information standard, time of day is represented as the number of seconds that have elapsed since the beginning of “GPS time,” 0000 Hours UTC, January 6<sup>th</sup>, 1980. GPS time is referenced to the Master Clock at the US Naval Observatory and steered to Coordinated Universal Time (UTC). UTC is the current time of day at the time zone local to Greenwich, England, and is the time source we use to set our clocks.

The cycle of the seasons, technically known as the tropical year, is approximately 365.2422 days. Using the Gregorian calendar we adjust for the fractional day by occasionally adding an extra day to the year. Every fourth year is a leap year, except that three leap years in every 400 are skipped (the centennial years not divisible by 400). With this scheme there are 97 leap years in each 400 year span, yielding an average year that is 365.2425 days long.

UTC is occasionally adjusted by one second increments to ensure that the difference between a uniform time scale defined by atomic clocks does not differ from the Earth’s rotational time by more than 0.9 seconds. The timing of occurrence of these “leap seconds” is determined by careful observations of the Earth’s rotation; each is announced months in advance. On the days it is scheduled to occur, the leap second is inserted just following 12:59:59 PM UTC.

UTC can be directly computed from the count of GPS seconds since January 6<sup>th</sup>, 1980 by subtracting from it the count of leap seconds that have occurred since the beginning of GPS time. In the months just following January 1, 1999, this offset was 13 seconds.

This protocol defines various time-related events and activities, including starting times for programs, text display, changes to VCTs, and others. Two methods of time distribution are used in headend systems. One method derives time in the form of GPS seconds from GPS Hosts. These Hosts also provide current GPS/UTC offset data. The second method of time distribution relies on the Internet Standard Network Time Protocol (NTP). NTP servers provide output in the form of UTC time, and do not provide GPS/UTC offset data. The Standard-compliant Host is synchronized to system time by the System Time Table, which provides time either in the form of GPS seconds since week zero of GPS time, January 6<sup>th</sup>, 1980, or directly in UTC time. The interpretation depends on the value of the GPS/UTC offset field. The special value of zero is used to indicate that the system is being driven by a UTC time source directly, and that GPS/UTC offset data is not available.

### *System Time*

GPS satellites typically output GPS time in a format consisting of a week count ( $T_w$ ) and a seconds within the week count ( $T_s$ ), where week zero is defined as starting January 6<sup>th</sup>, 1980. For purposes of building the System Time Table, the following formula may be used:

$$T = (T_w * 604,800) + T_s$$

There are 604,800 seconds per week.

When converting between GPS seconds and current local time in hours/minutes/seconds, the following factors must be taken into account:

- **GPS to UTC offset** — Given a time represented as GPS seconds, the Host first subtracts the GPS/UTC offset to convert to UTC.
- **1980** — The first year of GPS time started on January 6<sup>th</sup>, yielding 361 days in the first year (1980 was also a leap year).
- **Leap years** — The number of leap years that occurred between the current GPS second and 1980 must be accounted for. A leap year is a year whose number is evenly divisible by four, or, in the case of century years, by 400.

*Note:* According to this rule, the year 2000 *is* a leap year even though it is a century year, because it is also divisible by 400.

- **Time zones** — Time zones are signed integer values in the range -12 to +13 hours, where positive numbers represent zones east of the Greenwich meridian and negative numbers west of it. Pacific Standard Time (PST) is 8 hours behind standard time, and Eastern Standard Time (EST) is 5 hours behind. The system defined by this Service Information standard accommodates time zones that are not an integral number of hours offset from Greenwich by defining time zone as an 11-bit signed integer number in units of minutes. To convert to local time, the time zone is added to Greenwich time using signed integer arithmetic.

- **Daylight savings time** — If applicable, daylight savings time must be taken into account. On a unit by unit basis, each Host may be given a definition for when daylight savings time is entered into in Spring, and when it is exited in Fall. Entry/exit points are given as absolute times (GPS seconds), and hence are given in one second resolution.

### *Transmission Format for Event Times*

In this messaging protocol, the absolute time of action is specified for most events in terms of an unsigned 32-bit integer number, the count of GPS seconds since January 6<sup>th</sup>, 1980. This count does not wrap until after the year 2116<sup>18</sup>.

### *Handling of Leap Second Events*

In this Service Information protocol, times of future events (such as event start times in the EIT) are specified the same as time of day, as the count of seconds since January 6<sup>th</sup>, 1980. Converting an event start time to UTC and local time involves the same calculation as the conversion of system time to local time. In both cases, the leap seconds count is subtracted from the count of GPS seconds to derive UTC.

GPS time is used to represent future times because it allows the Host to compute the time interval to the future event without regard for the possible leap second that may occur in the meantime. Also, if UTC were to be used instead, it wouldn't be possible to specify an event time that occurred right at the point in time where a leap second was added. UTC is discontinuous at those points.

Around the time a leap second event occurs, program start times represented in local time (UTC adjusted by local time zone and [as needed] daylight savings time) may appear to be off by plus or minus one second. Generating equipment may use one of two methods to handle leap seconds.

In method A, generating equipment does not anticipate the future occurrence of a leap second. In this case, prior to the leap second, program start times will appear correct. An event starting at exactly 10 AM will be computed as starting at 10:00:00. But just following the leap second, that same event time will be computed as 9:59:59. The generating equipment should re-compute the start times in all the EITs and introduce the leap second correction. Once that happens, and Hosts have updated their EIT data, the computed time will again show as 10:00:00. In this way the disruption can be limited to a matter of seconds.

In method B, generating equipment does anticipate the occurrence of a leap second, and adjusts program start times for events happening after the new leap second is added. If the leap second event is to occur at midnight tonight, an event starting at 10 AM tomorrow will be computed by receiving equipment as starting at 10:00:01.

For certain types of events, the precision of method B is necessary. By specifying events using a time system that involves no discontinuities, difficulties involving leap seconds are

---

<sup>18</sup> Prior to that time, all initial Receivers will surely be out of service, and new ones can be designed to handle the wrap condition.

avoided. Events such as program start times do not require that level of precision. Therefore, method A works well.

### *Handling of Leap Second Events*

Consider the following example. Times are given relative to UTC, and would be corrected to local time zone and daylight savings time as necessary.

- ◆ Time of day (UTC): 1:00 PM, December 30<sup>th</sup>, 1998
- ◆ Event start time (UTC): 2:00 PM, January 2<sup>nd</sup>, 1999
- ◆ A leap second event will occur just after 12:59:59 PM on December 31<sup>st</sup>, 1998
- ◆ Leap seconds count on December 30<sup>th</sup> is 12

The data in the System Time Table is:

- ◆ GPS seconds = 599,058,012 = 0x23B4E65C
- ◆ GPS to UTC offset = 12

Using method A (upcoming leap second event is not accounted for):

- ◆ Event start time in EIT: 599,320,812 = 0x23B8E8EC
- ◆ Converted to UTC: 2:00:00 PM, January 2<sup>nd</sup>, 1999
- ◆ Number of seconds to event: 262,800 = 73 hours, 0 minutes, 0 seconds

Using method B (upcoming leap second event is anticipated):

- ◆ Event start time in EIT: 599,320,813 = 0x23B8E8ED
- ◆ Converted to UTC: 2:00:01 PM, January 2<sup>nd</sup>, 1999
- ◆ Number of seconds to event: 262,801 = 73 hours, 0 minutes, 1 second

Note that using method B, the number of seconds to event is correct, and does not need to be recomputed when the leap seconds count moves from 12 to 13 at year-end.

**ANNEX D**  
**PACKET RATES**  
**(Normative)**

**D.1 Maximum cycle times**

Table D.1 lists the maximum cycle time for Service Information table sections for out-of-band cable operation, when the indicated table is present.

**Table D.1 Maximum cycle time for the STT, MGT, S-VCT, L-VCT and RRT**

Table Section	STT	MGT	S-VCT	L-VCT	RRT
Cycle time	1 min.	500 msec.	2 min.	2 min.	1 min.

**D.2 Maximum Transmission Rates**

Table D.2 lists the maximum transmission rate for SI packet streams.

**Table D.2 Maximum rate for each packet stream**

PID	SI_base PID	any AEIT/AETT PID
Rate (bps)	150,000	150,000

**D.3 MINIMUM Transmission Rates**

Table D.3 lists the minimum transmission rate for SI packet streams. Minimum per-PID bit rates are required to ensure efficiency of recovery of EPG data covering the current time period (3 hours minimum) across an Extended Channel Interface, given the small number of PID values that can be used concurrently.

**Table D.3 Minimum rate for each packet stream**

PID	AEIT-0,1/AETT-0,1 PID
Rate (bps)	10,000

## ANNEX E

### DAYLIGHT SAVINGS TIME CONTROL

#### (Informative)

In order to convert GPS into local time, the Host needs to store a time offset (from GPS to local time) in local memory and an indicator as to whether daylight savings is observed. These two quantities can be obtained from the user interface (indicating time zone and daylight savings observance) or from the conditional access system, if present, and stored in non-volatile Host memory.

Since there is a common time (GPS) transmitted in SI, a mechanism to indicate when the Host should switch into (or out of) daylight savings time at the appropriate local time can be very useful. Once all the Hosts have transitioned at their local times, the entire system can be shifted into daylight savings time. This is accomplished by appropriate setting of the `daylight_savings` in the `daylight_savings_time_descriptor()` the STT. The basic use of daylight savings fields through the year is shown in Table E.1.

**Table E.1 Basic Use of Daylight Savings Fields Through the Year**

Conditions	DS status	DS_day of_month	DS_hour
At the beginning of the year (January) daylight savings is off. This is the status of the fields until:	0	0	0
<input type="checkbox"/> When the transition into daylight savings time is within less than one month, the DS_day_of_month field takes the value day_in, and the DS_hour field takes the value hour_in. The DS_status bit is 0 indicating it is not yet daylight savings time. (The transition is to occur on the day_in day of the month at hour=hour_in; for example, if the transition were on April 15 at 2 a.m., then day_in=15 and hour_in=2)	0	day_in	hour_in
<input type="checkbox"/> After all time zone daylight transitions (within the span of the network) have occurred, the DS_status bit takes the value 1, indicating that daylight savings time is on. The DS_day_of_month field and the DS_hour field take the value 0. (In the U.S., this transition has to occur no later than 7 p.m. Pacific Time on the day day_in). This is the status of the fields until:	1	0	0
When the transition out of daylight savings time is within less than one month, the DS_day_of_month field takes the value day_out, and the DS_hour field takes the value hour_out. The DS_status bit is 1 indicating it is still daylight savings time. (The transition is to occur on the day_out day of the month at hour=hour_out; for example, if the transition were on October 27 at 2 a.m., then day_out=27 and hour_out=2)	1	day_out	hour_out
<input type="checkbox"/> After all time zones (within the span of the network) have shifted out of daylight savings time, the DS_status bit takes the value 0, indicating that daylight savings time is off. The DS_day_of_month field and the DS_hour field take the value 0. (In the U.S., this transition has to occur no later than 7 p.m. Pacific Time on the day day_out). This finishes the cycle.	0	0	0

## ANNEX F

## STANDARD HUFFMAN TABLES FOR TEXT COMPRESSION

## (Normative)

This Annex describes the compression method adopted for the transmission of English-language text strings in PSIP. The method distinguishes two types of text strings: titles and program descriptions. For each of these types, Huffman tables are defined based on 1st-order conditional probabilities. Section F.2 defines standard Huffman encode and decode tables optimized for English-language text such as that typically found in program titles. Section F.3 defines Huffman encode and decode tables optimized for English-language text such as that typically found in program descriptions. Hosts supporting the English language are expected to support decoding of text using either of these two standard Huffman compression tables.

The encode tables provide necessary and sufficient information to build the Huffman trees that need to be implemented for decoding. The decode tables described in Tables F.5 and F.7 are a particular mapping of those trees into a numerical array suitable for storage. This array can be easily implemented and used with the decoding algorithm. However, the user is free to design its own decoding tables as long as they follow the Huffman trees and rules defined in this Annex.

**F.1 Character Set Definition**

This compression method supports the full ISO/IEC 8859-1 (Latin-1) character set, although only characters in the ASCII range (character codes 1 to 127) can be compressed. The following characters have special definitions:

**Table F.1 Characters with Special Definitions**

Character	Value (Decimal)	Meaning
String Terminate (ASCII Null)	0	The <i>Terminate</i> character is used to terminate strings. The Terminate character is appended to the string in either compressed or uncompressed form.  The first encoded character in a compressed string is encoded/decoded from the Terminate sub-tree. In other words, when encoding or decoding the first character in a compressed string, assume that the previous character was a Terminate character.
Order-1 Escape (ASCII ESC)	27	Used to escape from first-order context to uncompressed context. The character which follows the Escape character is uncompressed.

### F.1.1 First Order Escape

The order-1 Huffman trees are *partial*, that is, codes are not defined for every possible character sequence. For example, the standard decode tables do not contain codes for the character sequence *qp*. When uncompressed text contains a character sequence which is not defined in the decode table, the order-1 escape character is used to escape back to the uncompressed context. Uncompressed symbols are coded as 8-bit ASCII (Latin I). For example, the character sequence *qpa* would be coded with *compressed q*, *compressed ESC*, *uncompressed p*, *compressed a*.

First-order escape rules for compressed strings:

- Any character which follows a first-order escape character is an uncompressed (8-bit) character. (Any character which follows an uncompressed escape character is compressed).
- Characters (128 .. 255) cannot be compressed.
- Any character which follows a character from the set (128 .. 255) is uncompressed.

### F.1.2 Decode Table Data Structures

Decode tables have two sections:

- **Tree Root Offset List:** Provides the table offsets, in *bytes* from the start of the decode table, for the roots of the 128 first-order decode trees. The list is contained in bytes (0 .. 255) of the decode table, and is defined by the first “for” loop in Table F.1.
- **Order-1 Decode Trees:** Each and every character in the range (0 .. 127) has a corresponding first-order decode tree. For example, if the previous character was "s", then the decoder would use the "s" first-order decode tree (decode tree #115) to decode the next character (ASCII "s" equals 115 decimal). These 128 decode trees are delimited by the second “for” loop in Table F.2.

Decode tables have the following format:

**Table F.2 Decode Table Format**

Syntax	Bits	Format
decode_table() { for (i==0; i<128; i++) { <b>byte_offset_of_char_i_tree_root</b> } for (i==0; i<128; i++) { <b>character_i_order_1_tree()</b> } }	16	uimsbf
	8*M	

Note that even though the ISO Latin-1 character set supports up to 256 characters, only the first 128 characters may be represented in compressed form.

### F.1.2.1 Tree Root Byte Offsets

**byte\_offset\_of\_character\_i\_tree\_root**—A 16-bit unsigned integer specifying the location, in bytes from the beginning of the decode table, of the root for the  $i^{\text{th}}$  character's order-1 tree.

### F.1.2.2 Order-1 Decode Trees

Order-1 decode trees are binary trees. The roots of the decode trees are located at the table offsets specified in the tree root offset list. The left and right children of a given node are specified as *word* offsets from the root of the tree (a *word* is equivalent to two bytes).

Decode trees have the following format:

**Table F.3 Decode Tree Format**

Syntax	Bits	Format
<pre> character_i_order_1_tree() {   for (j=0; j&lt;N; j++) {     left_child_word_offset_or_char_leaf     right_child_word_offset_or_char_leaf   } } </pre>	8	uimsbf
	8	uimsbf

**left\_child\_word\_offset\_or\_character\_leaf**—An 8-bit unsigned integer number with the following interpretation: If the highest bit is cleared (i.e. bit 7 is zero), the number specifies the offset, in words, of the left child from the root of the order-1 decode tree; if the highest bit is set (bit 7 is one), the lower 7 bits give the code (e.g., in ASCII) for a leaf character.

**right\_child\_word\_offset\_or\_character\_leaf**—An 8-bit unsigned integer number with the following interpretation: If the highest bit is cleared (i.e. bit 7 is zero), the number specifies the offset, in words, of the right child from the root of the order-1 decode tree; if the highest bit is set (bit 7 is one), the lower 7 bits give the code (e.g., in ASCII) for a leaf character.

Each node (corresponding to one iteration of the for-loop) has a byte for the left child or character, and a byte for the right child or character.

Characters are *leaves* of the order-1 decode trees, and are differentiated from intermediate nodes by the byte's most significant bit. When the most significant bit is set, the byte is a character leaf. When the most significant bit is not set, the byte contains the tabular word offset of the child node.

**F.2 Standard Compression Type 1 Encode/Decode Tables**

The following encode/decode tables are optimized for English-language program title text. These tables correspond to multiple\_string\_structure() with compression\_type value 0x01, and a mode equal to 0xFF.

**Table F.4 English-language Program Title Encode Table**

### F.3 Standard Compression Type 2 Huffman Encode/Decode Tables

The following encode/decode tables are optimized for English-language program description text. These tables correspond to multiple\_string\_structure() with compression\_type value 0x02, and mode equal to 0xFF.

**Table F.6 English-language Program Description Encode Table**
