# Optimizing Value from Service Provider Wi-Fi in a Converged World

**Mike Darling**

Principal Engineer  
Shaw Communications

## Over 900k Access Points

Consisting of indoor and outdoor service provider APs as well as secondary SSIDs from business and consumer Wi-Fi APs

## Wide Availability

Available, free of charge to broadband subscribers, wireless subscribers and to the public for the duration of the COVID-19 pandemic

## Unlimited Data

Wi-Fi data is not limited, speed caps are 30/5Mbps for broadband subscribers and 100/10Mbps for wireless subscribers

## Strategic Purpose

### Customer Value

At your  
Destination

At Home

On the Go

Subscribers want access to their broadband applications at home, on the go and at their destinations

- Wireline at home
- Wireless on the go
- Service provider Wi-Fi at your destination

### What is the user experience?

Anecdotal accounts pointed towards some subscribers connecting to the network and not being able to connect to their applications

### Is the network used as intended?

The network was meant to extend subscriber's services, but were they replacing them? Was the network being accessed in unintended ways?

# Service Provider Wi-Fi | Time of Day

Wireline network peaks in the late evening when subscribers are at home

Wireless network peaks in the late afternoon when subscribers are on the go

Wi-Fi behaves like the wireless network with a delayed start to the day

## Cumulative Distribution Functions

Wireline and Wi-Fi consumption are both highly weighted toward a small percentage of users, Wi-Fi slightly more so. 20% of wireline subscribers account for 75% of consumption, while 20% of Wi-Fi subscribers account for 85% of consumption

## Application Use

Both wireline and Wi-Fi network traffic is dominated by video. YouTube accounts for the most Wi-Fi consumption with shorter content designed for smaller screens, while Netflix dominates wireline consumption due to longer content and larger screens

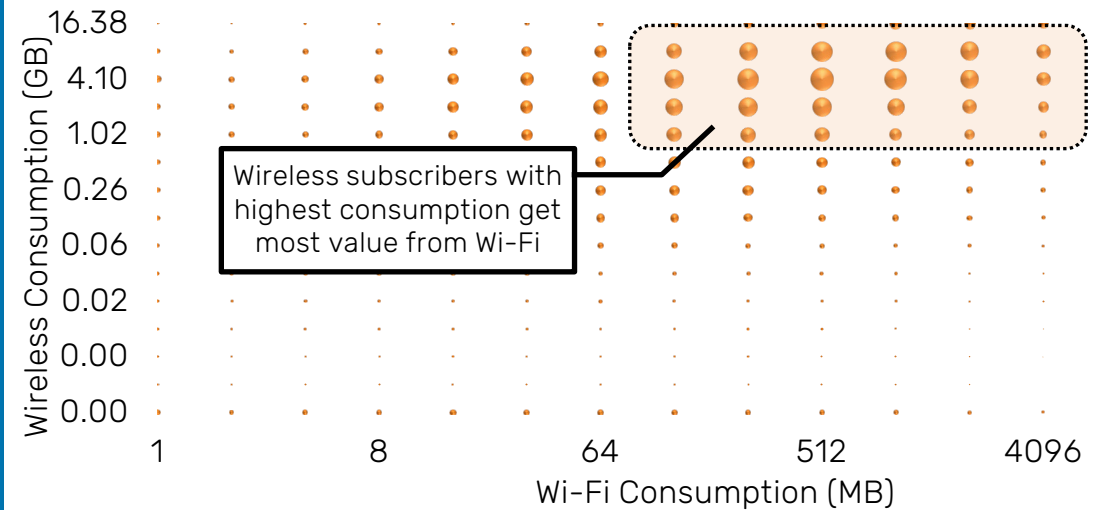

## Contrasting Wireline & Wi-Fi Consumption

Bubble size indicates number of subscribers

## Contrasting Wireless & Wi-Fi Consumption

Bubble size indicates number of subscribers

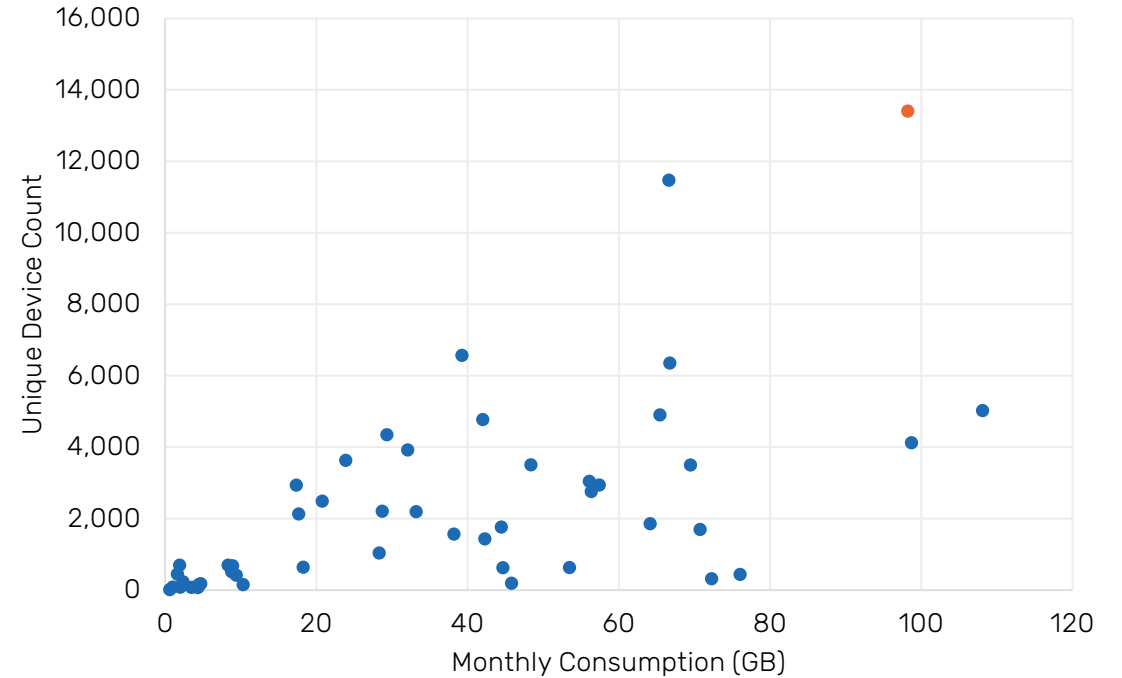

- Subscribers with heavy Wi-Fi consumption tend to also have heavy wireline/wireless consumption

- Wi-Fi consumption is similar between wireline and wireless subscribers, but wireline accounts have two devices on average per account

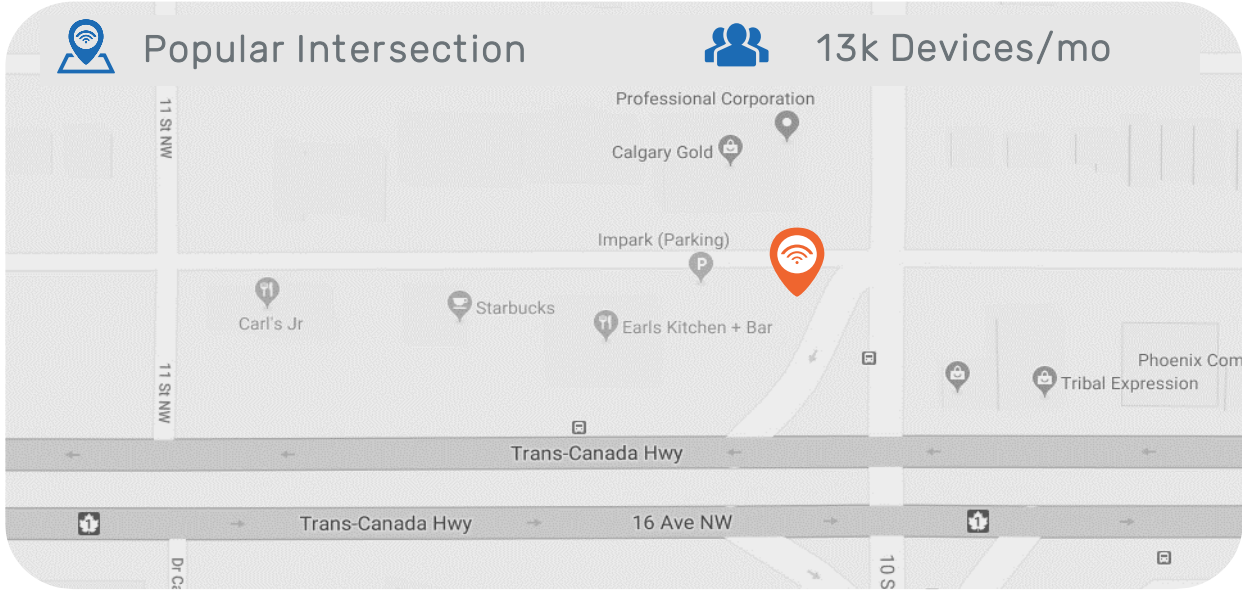

- Wi-Fi APs were installed at many types of venues
- Transportation, Hotels and Wi-Fi Zones had higher consumption per AP than other venues
- One Wi-Fi Zone in particular was thought to be causing customer experience issues and was investigated

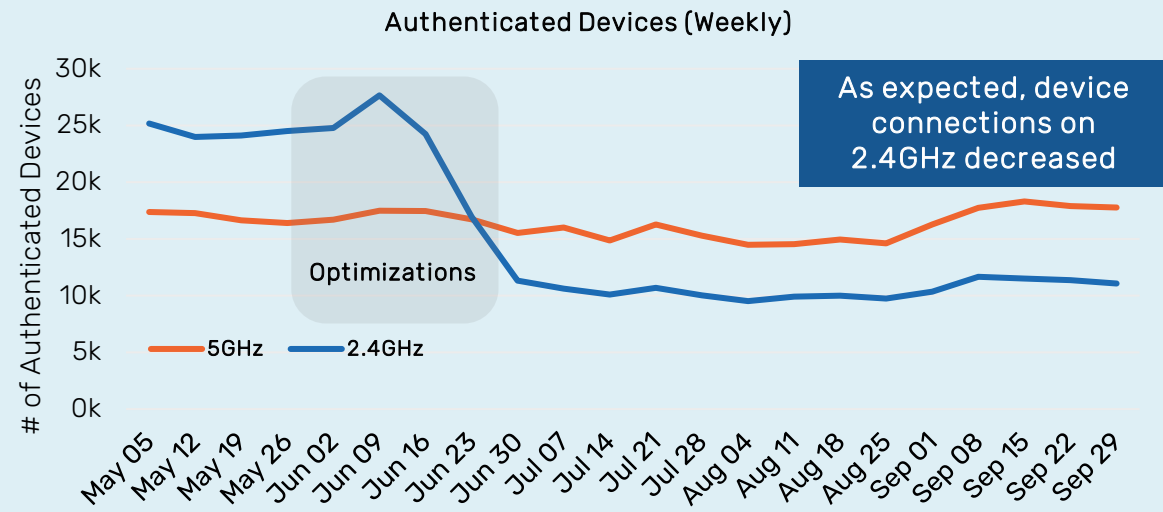

- The venue coverage was provided by outdoor strand mounted APs
- The variation between APs in terms of unique devices and monthly consumption was large
- The AP in the top right was further investigated

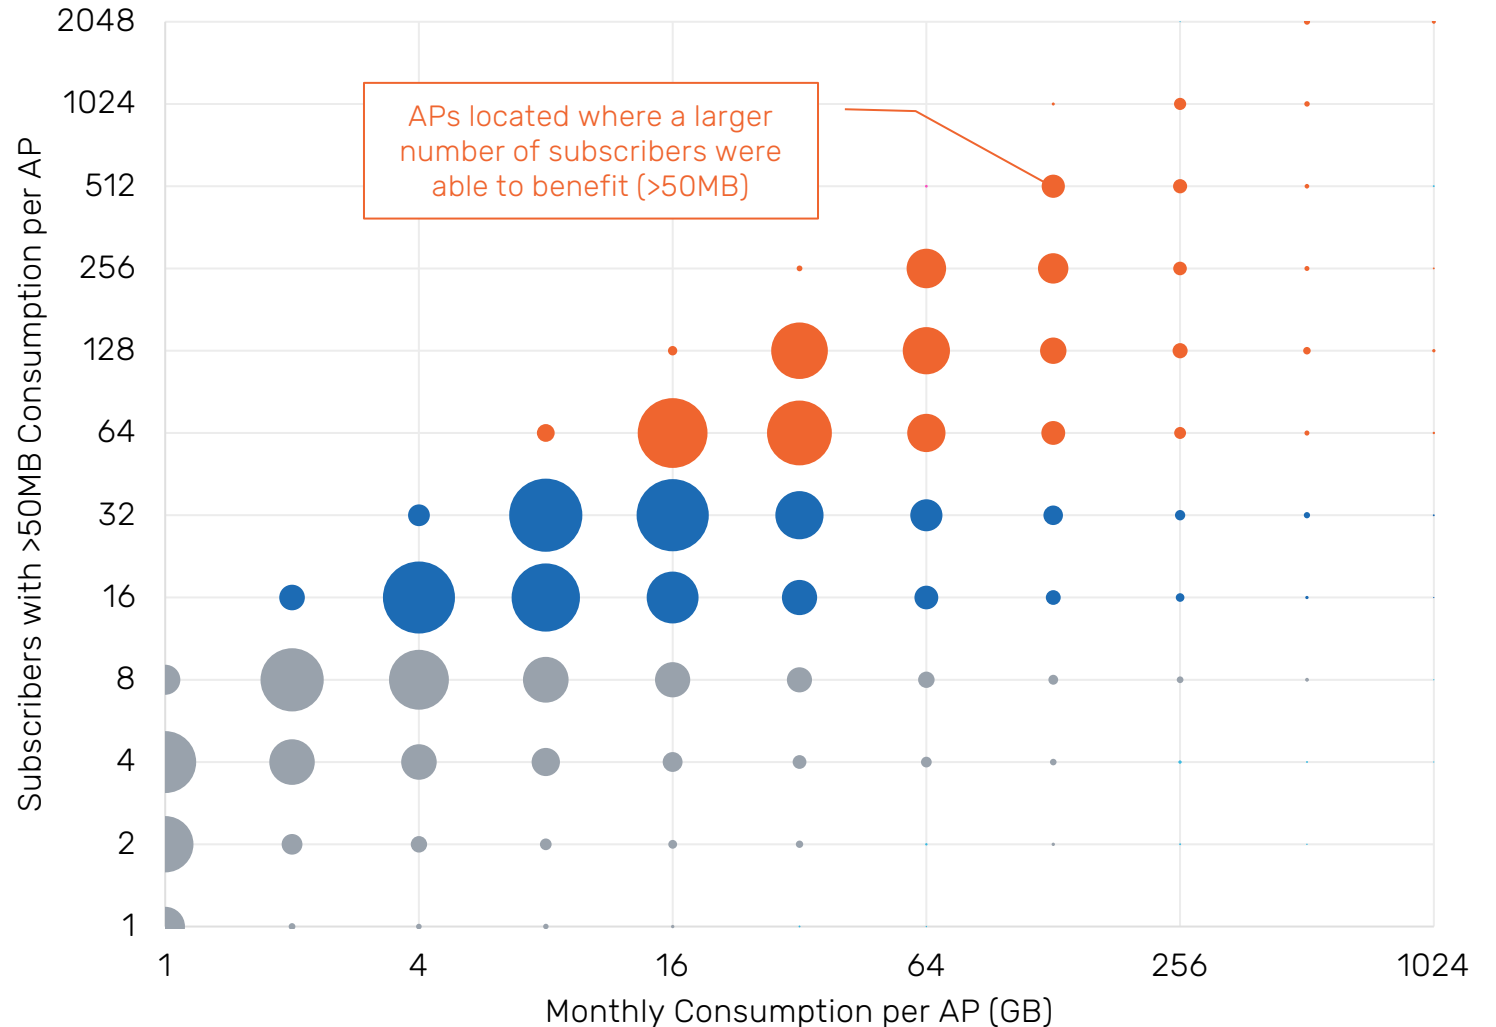

# Service Provider Wi-Fi | Venue Analysis

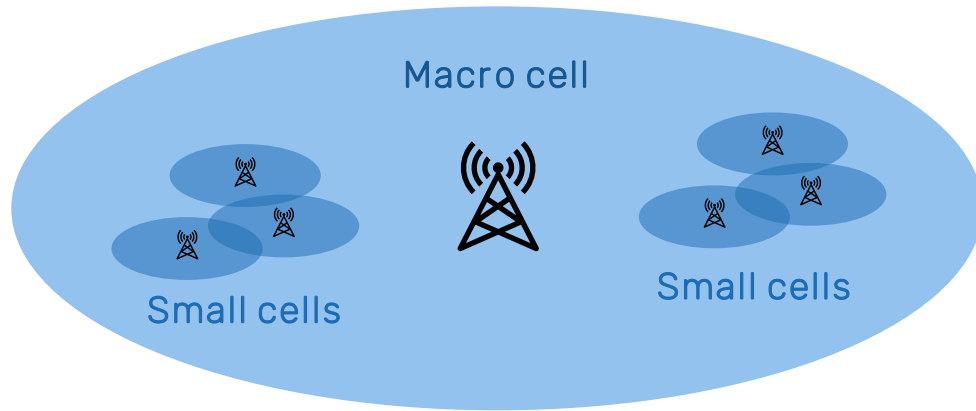

Optimizations prevented users with very low signal levels from connecting

- A methodology was required to decide the priority in upgrading APs to Wi-Fi 6
- The decision was made to use number of subscribers that consumed more than 50MB per month at the AP
- 50MB was chosen as it provides tangible offload as opposed to low consumption tasks such as checking email
- Goal is to focus investments where customers get the most value

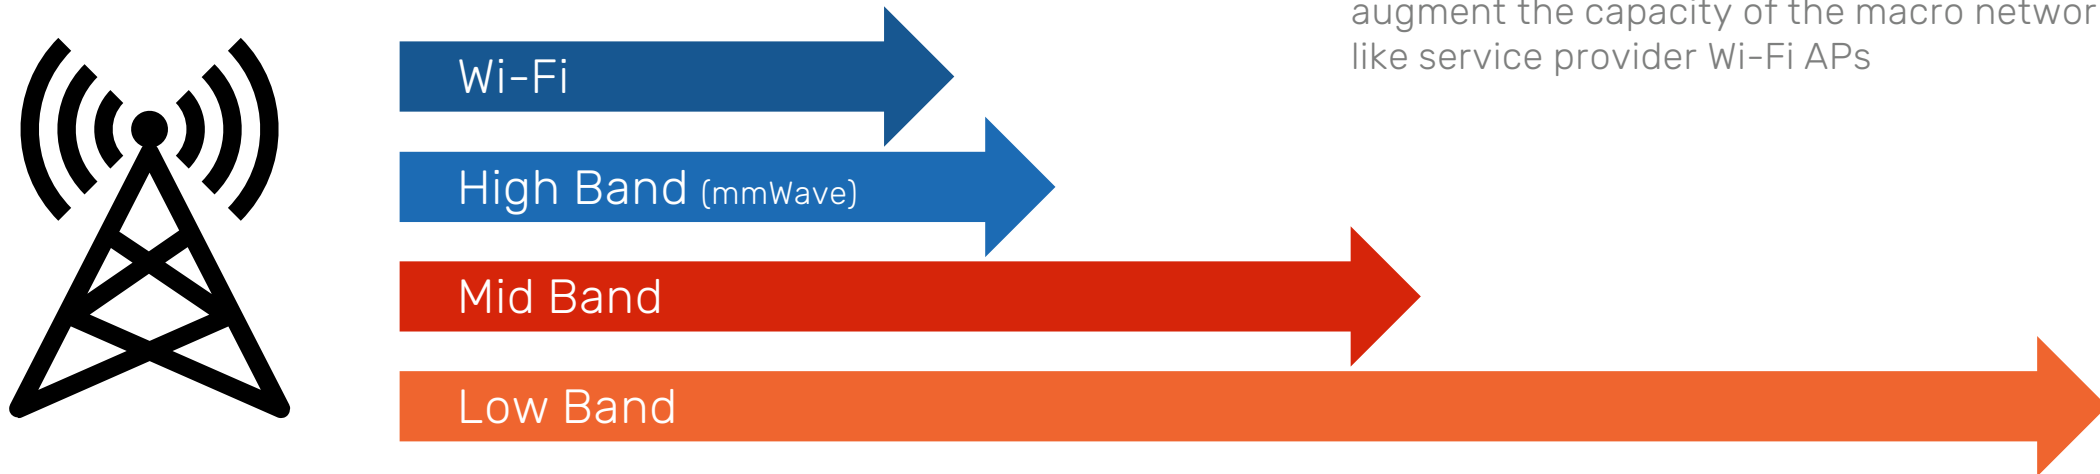

## Small cells are similar to Wi-Fi APs

When it comes to capacity and coverage small cells, especially when using mmWave spectrum, look more like Wi-Fi APs than macro cells

## Requirement for placement

Small cells will be deployed where people gather to augment the capacity of the macro network, just like service provider Wi-Fi APs

- Both service provider Wi-Fi and small cells were deployed to a venue
- RF coverage planning was done separately, but resulted in similar placement
- Wireless subscribers, who had access to both networks, had 4.4X more consumption on the Wi-Fi network than the small cell network

## Service Provider Wi-Fi

## Home Hotspot
