AMERICAN NATIONAL STANDARD

ANSI/SCTE 25-2 2017 (R2022)

**Hybrid Fiber Coax Outside Plant Status Monitoring –
Media Access Control (MAC) Layer Specification v1.0**

NOTICE

The Society of Cable Telecommunications Engineers (SCTE) Standards and Operational Practices (hereafter called “documents”) are intended to serve the public interest by providing specifications, test methods and procedures that promote uniformity of product, interoperability, interchangeability, best practices, and the long term reliability of broadband communications facilities. These documents shall not in any way preclude any member or non-member of SCTE from manufacturing or selling products not conforming to such documents, nor shall the existence of such standards preclude their voluntary use by those other than SCTE members.

SCTE assumes no obligations or liability whatsoever to any party who may adopt the documents. Such adopting party assumes all risks associated with adoption of these documents and accepts full responsibility for any damage and/or claims arising from the adoption of such documents.

NOTE: The user’s attention is called to the possibility that compliance with this document may require the use of an invention covered by patent rights. By publication of this document, no position is taken with respect to the validity of any such claim(s) or of any patent rights in connection therewith. If a patent holder has filed a statement of willingness to grant a license under these rights on reasonable and nondiscriminatory terms and conditions to applicants desiring to obtain such a license, then details may be obtained from the standards developer. SCTE shall not be responsible for identifying patents for which a license may be required or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention.

Patent holders who believe that they hold patents which are essential to the implementation of this document have been requested to provide information about those patents and any related licensing terms and conditions. Any such declarations made before or after publication of this document are available on the SCTE web site at <https://scte.org>.

Introduction

This document is identical to SCTE 25-2 2008 except for informative components which may have been updated such as the title page, NOTICE text, headers and footers. No normative changes have been made to this document.

The Hybrid Fiber Coax (HFC) Outside Plant (OSP) Media Access Control (MAC) Layer Specification is part of the suite of specifications developed by the Hybrid Management Sub-Layer (HMS) subcommittee under the SCTE. The purpose of the HMS specifications is to support the design and implementation of interoperable management systems for evolving HFC cable networks. The HMS Media Access Control (MAC) Layer Specification describes the messaging and protocols implemented at the Data Link Layer (DLL), Layer 2 in the 7-layer ISO-OSI reference model, that support reliable and efficient communications between HMS-compliant transponders interfacing to managed OSP network elements (NEs) and a centralized headend element (HE).

2.1 Scope

This specification describes the MAC layer protocols that must be implemented between all *Type 2* and *Type 3* compliant OSP HMS transponders on the HFC plant and the controlling equipment in the headend to support bandwidth management and reliable communications. Any exceptions to compliance with this specification will be specifically noted in this document as necessary. Refer to **Table 1** for a full definition of the Type Classifications.

2.2 Transponder Type Classifications

Transponder type classifications referenced within the HMS suite of specifications are defined in **Table 1**.

Table 1: Transponder Type Classifications

Type	Description	Application
<i>Type 0</i>	Refers to legacy transponder equipment which is incapable of supporting the HMS specifications.	<ul style="list-style-type: none"> • This transponder interfaces with legacy network equipment through proprietary means. • This transponder could be managed through the same management applications as the other types through proxies or other means at the headend.
<i>Type 1</i>	Refers to stand-alone transponder equipment (legacy or new) which can be upgraded to support the HMS specifications.	<ul style="list-style-type: none"> • This transponder interfaces with legacy network equipment through proprietary means. • Type 1 is a standards-compliant transponder (either manufactured to the standard or upgraded) that connects to legacy network equipment via a proprietary interface.
<i>Type 2</i>	Refers to a stand-alone, HMS-compliant transponder.	<ul style="list-style-type: none"> • This transponder interfaces with network equipment designed to support the electrical and physical specifications defined in the HMS standards. • It can be factory or field-installed. • Its RF connection is independent of the monitored NE.
<i>Type 3</i>	Refers to a stand-alone or embedded, HMS-compliant transponder.	<ul style="list-style-type: none"> • This transponder interfaces with network equipment designed to support the electrical specifications defined in the HMS standards. • It may or may not support the physical specifications defined in the HMS standards. • It can be factory-installed. It may or may not be field-installed. • Its RF connection is through the monitored NE.

2.3 HMS Reference Architecture Forward and Return Channel Specifications

The reference architecture for the HMS suite of specifications is illustrated in **Figure 1**.

Figure 1: HMS Reference Architecture Diagram

** The diplexer filter may be included as part of the network element to which the transponder interfaces, or it may be added separately by the network operator.*

All quantities relating to forward channel transmission or reverse channel reception are measured at point A in **Figure 1**. All quantities relating to forward channel reception or reverse channel transmission are measured at point B for two-port devices and point C for single-port devices as shown in **Figure 1**.

2.4 HMS Specification Documents

A list of documents in the HMS specifications family is provided in **Table 2**.

3 Media Access Control Layer Specification

3.1 Introduction

3.1.1 Overview

This section describes version 1.0 of the SCTE HMS MAC protocol. Some of the SCTE HMS MAC protocol features include:

- Support for transaction-based message exchange over the HFC forward and return RF channels. Transactions can be initiated by either the HE or the NE.
- Support for transport of multiple network PDU types over the HFC forward and return RF channels including, but not limited to, IP over Serial and SNMP over Serial.
- Extensions provided to support future transport of other network PDU types.
- Efficient use of HFC forward and return RF spectrum through central HE management of NE transmission opportunities.

3.1.2 Definitions and Conventions

3.1.2.1 Separate Forward and Return Channels

The one-way communication channel from the HE to a managed OSP NE is referred to as the *forward* channel. The one-way communication channel from a managed OSP NE to the HE is referred to as the *return* channel. Both the forward and the return channels are placed on specific center frequencies. The forward and return channels' center frequencies are different. Since the NEs only listen to the forward channel, they cannot listen to return channel transmissions from other NEs. This channel separation is a result of the sub-band split between the forward and return portions of the typical HFC plant spectrum.

3.1.2.2 Single Forward and Return Path Channels per MAC Layer Domain

To keep management of carrier frequencies simple, each HMS-based status monitoring system has a single forward channel and a single return channel. This does not preclude the use of multiple monitoring systems, each with its own individual forward and return RF channels.

A MAC layer domain consists of a single forward RF channel and a single return RF channel over which a single HMS MAC layer bandwidth allocation and management protocol operates. It includes a centralized HE and multiple HMS-compliant transponders interfacing to managed OSP NEs. The centralized HE may support multiple HMS-based status monitoring systems, i.e.: multiple MAC layer domains. Each OSP NE must only access a single forward channel and its associated single return channel; i.e.: it must only operate within a single HMS MAC layer domain.

3.1.2.3 Network Element (NE) Term Usage

The HMS MAC layer supports bandwidth management and reliable communications between a HE and multiple HMS-compliant transponders that interface to managed OSP NEs. Throughout this document, the terms “HMS-compliant transponder”, “transponder”, and “NE” are used interchangeably when describing the MAC processes that support the exchange of data or other information between two or more entities at the DLL.

3.1.2.4 Packet

A packet is a unit of data exchanged between the HE and any of a number of managed OSP NEs at the DLL. Packets are strings of bytes that can be sent contiguously or be separated by periods of silence. Document SCTE 25-1 *HMS Outside Plant Status Monitoring – Physical (PHY) Layer Specification v1.0* describes specific byte transmission modes that must be implemented in both forward and return channels. A MAC packet consists of a MAC header, a variable-length payload, and a frame check sequence (see Section 3.3).

3.1.2.5 Most Significant Byte

Unless otherwise specified, it is assumed throughout this document that the left-most entry in any numeric value is the most significant, i.e.: for the address represented as 12-34-56-78-9A-BC the left-most entry ‘12’ is the most significant value.

3.1.2.6 Byte Number Representation

Throughout this document, bits labeled ‘0’ are the least significant bits (LSBs) and bits labeled ‘7’ are the most significant bits (MSBs). The bits in a given byte will be described with bit 7 (MSB) at the left and bit 0 (LSB) at the right. This convention has been adopted for presentation purposes only and has no effect on the actual bit transmission order. Bit transmission order details are provided in Section 3.2 of this specification.

3.1.2.7 Reserved Bits

A number of bits are indicated with the word “Reserved” or the abbreviation “RSVD” in the various MAC packets described in this document. Any receiving NE must ignore these bits when implementing this version (1.0) of the HMS MAC protocol.

3.2 MAC Packet Transport

3.2.1 Byte Transmission Format

Bytes transmitted over both forward and return channels are ten bits in length. They contain one start bit, eight bits of data, and one stop bit. The start bit has binary value ‘0’, and the stop bit has binary value ‘1.’

3.2.2 Byte Transmission Order

Fields consisting of multiple bytes, i.e.: a MAC address, will have the most significant byte transmitted first. Any exceptions to this rule will be specifically noted in this document as necessary.

3.2.3 Bit Transmission Order

The LSB of a single byte, bit 0, is always transmitted first following the start bit. The MSB of a single byte, bit 7, is always transmitted last followed by the stop bit. The transmission order is summarized in **Figure 2**.

Figure 2: Bit Transmission Order

3.2.4 Transmission Timing

3.2.4.1 Forward Channel Packets

3.2.4.1.1 Timing

Forward channel packets must be transmitted in a manner such that,

1. No two bytes within a packet are separated by more than 3 ms, AND
2. The entire packet must be transmitted within 120% of the *shortest* time for that frame. The shortest time is defined as the time for transmission of the packet with no gaps between bytes.

3.2.4.2 Return Channel Packets

3.2.4.2.1 Front Porch

NE transmission of the first byte of a message shall begin within a window of two and five byte times after the transmitter power reaches 90% of its final value. Until the first byte is transmitted, the frequency will rest on the ‘mark’ frequency. This is standard Universal Asynchronous Receiver/Transmitter (UART) transmission. The front porch ensures that the receiving UART can be cleared of all framing errors prior to the start of reception of valid data.

3.2.4.2.2 Timing

Return channel packets must be transmitted in a manner such that no two bytes within a packet are separated by more than 260 μ s (1 byte time). All bits within a single byte shall be immediately contiguous; there shall be no gaps at bit boundaries within a byte.

3.3 MAC Packet Structure

MAC packets consist of a MAC header, a variable-length payload, and a two-byte frame check sequence. Packet structure and sizes are identical for both forward and return channel packets. MAC packet structure is illustrated in **Figure 3**.

Figure 3: MAC Packet Structure

All MAC packets must have the general format as described in **Table 3**.

Table 3: Generic MAC Packet Structure

Field Name	Length (bits)	Section
Synch	8	3.3.1
Control	8	3.3.2
Address	48	3.3.3
Sequence	8	3.3.4
Length	16	3.3.5
Payload	N	3.3.6
FCS	16	3.3.7

3.3.1 Synch

The Synch field consists of a single byte and identifies the start of the MAC layer packet. It shall be set to 0xA5.

3.3.2 Control

The Control field consists of a single byte and defines the type and format of the Payload field. The bit definition of the Control byte is shown in **Figure 4**. The Control field also serves, in conjunction with the Synch, Length and FCS fields, as a packet delimiter as described in Section 3.4.

Figure 4: MAC Header Control Byte – Bit Definition

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
RSVD3	RSVD2	RSVD1	RSVD0	Protocol			

3.3.2.1 Protocol (Bits 3:0)

The four-bit protocol field indicates the type of protocol to be used to interpret the payload field of the MAC layer packet. In addition, the protocol field allows the message service handler to pass messages with alternative protocol values to other upper layer processes without having to unravel the entire message. The value represented by the protocol field shall be as assigned in **Table 4**.

Table 4: Protocol Field Values

Description	Binary Value
MAC Management Message	0000
SNMP over Serial (see note below)	0001
IP over Serial	0010
SNMP Trap over Serial	0011
<i>Available for Future Use</i>	0100 to 1111*

*Protocol 0101 is not allowed to prevent accidental creation of a Synch byte (0xA5).

Note

This is SNMPv1 as defined by RFC 1157. However, the UDP and IP protocols are not used for this implementation. Thus, all references by RFC 1157 to UDP are not relevant. Section 3.2.4 of RFC 1157 explains how the SNMP mechanisms are suitable over different transport protocols. Sections 4 and 4.1 of RFC 1157 explain this further. In fact, in Section 4.1, the RFC states: “Other transport services may be used to support the SNMP.”

3.3.2.2 RSVDx (Bits 7:4)

The bits identified as RSVD are reserved for future use. They must be set to 0.

3.3.3 Address

The Address field consists of six bytes. It is used to address devices on a unicast, multicast, or broadcast basis. The address field follows the IEEE Organizationally Unique Identifier (OUI) Std 802 usage for a Universal address. For clarity, this document conforms to the address documentation suggested by the IEEE as follows:

1. Each byte is represented as a two digit hexadecimal numeral (with no radix identification) using leading zeroes where the first (left-most) digit of the pair is the most significant.
2. Each byte is separated by hyphens, with the most significant byte in the left-most position.

An example address is 00-AA-BB-00-43-21.

A Universal address is a sequence of six bytes. The first three take the values of the three bytes of the OUI in order. The last three bytes are administered by the assignee. The binary representation of an address is formed by taking each byte in order and expressing it as a sequence of eight bits, LSB to MSB, left to right. For example, the OUI AC-DE-48 could be used to generate the address

AC-DE-48-00-00-80

Whose binary representation is:

First Byte of OUI	Second Byte of OUI	Third Byte of OUI	0000 0000	0000 0000	0000 0001
0011 0101	0111 1011	0001 0010			
I/G Address Bit					
LSB MSB	LSB MSB	LSB MSB	LSB MSB	LSB MSB	LSB MSB
C A	E D	8 4	0 0	0 0	0 8

The first (left-most) bit in the binary representation of the MAC address is the I/G (Individual/Group) Address Bit. This bit is the LSB of the most significant byte. When set to 0 as shown above, it indicates an individual address. It may be set to 1 in an address allocated by the assignee to indicate that that address is a group address. For example, the same OUI above could be used to generate the Group Address

AD-DE-48-00-00-80

First Octet of OUI	Second Octet of OUI	Third Octet of OUI	0000 0000	0000 0000	0000 0001
1011 0101	0111 1011	0001 0010			
I/G Address Bit					
LSB MSB	LSB MSB	LSB MSB	LSB MSB	LSB MSB	LSB MSB
D A	E D	8 4	0 0	0 0	0 8

The address shall be transmitted most significant byte first and least significant byte last.

3.3.3.1 Unicast

The Unicast address is the unique address assigned to a particular NE. An NE transmitting a message places its unicast address in the Address field, most significant byte first. This address is completely unique across all manufacturers. By definition, the I/G bit is set to 0.

Each vendor shall obtain an address prefix, or OUI, from the IEEE and assign a unique address using this prefix to each HMS-compliant transponder at time of manufacture. This is the Unicast address for that NE. This document places no restriction on the number of OUIs a single manufacturer may obtain as the IEEE governs that. An OUI assignment allows the assignee to generate approximately 16 million addresses by varying the last three octets.

3.3.3.2 Broadcast

A message with a Broadcast address is intended for all NEs that receive it. All NEs must support the Broadcast address. The Broadcast address is FF-FF-FF-FF-FF-FF.

3.3.3.3 Multicast

The Multicast address follows the IEEE Std 802 for indicating a Group Address; i.e., the I/G Address Bit is set to 1.

A Multicast address defines a group to which zero, one, or more than one NE has been assigned by a higher level management system. A NE maintains a list of multicast addresses to which it will respond. A NE is a member of a particular multicast group if at least one of its provisioned multicast addresses matches that particular multicast address. The assignment and usage of multicast addresses is out of the scope of this specification. However, examples might be fault isolation, frequency changes, and firmware downloads.

All NEs must support a minimum of four (4) multicast addresses not counting the Broadcast address. This specification places no maximum limit on the number of multicast address groups a NE may support.

Multicast addresses are *not* assigned at manufacture. The network provider provisions multicast addresses into the NE. The method for this provisioning is out of the scope of this specification. To avoid accidental assignment to the wrong multicast address, all multicast addresses held at the NE shall default to the Broadcast address prior to provisioning.

3.3.4 Sequence

The HMS MAC protocol is transaction-based; i.e., every originating message from a “requestor” has a corresponding response from the “responder” regardless of which device originated the message. The Sequence field consists of a single byte and defines a message sequence number to ensure message exchanges are synchronized. In order to handle possible loss of messages in either the forward or the return channel, and to avoid duplication of messages at the application

layer, all messages have a sequence number. The bit definition of the Sequence byte is shown in **Figure 5**.

Figure 5: MAC Header Sequence Byte – Bit Definition

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
SYN	MSGSEQ						

3.3.4.1 MSGSEQ (Bits 6:0)

The 7-bit MSGSEQ field indicates the message sequence number. Sequence numbers are generated by either the HE or NE. Sequence number generation, modification and elicited behavior must conform to the following rules:

1. HE-originated transactions will have bit 6 of the MSGSEQ field set to 1. Thus, the range for HE-generated sequence numbers is 0x40 through 0x7F with wraparound to 0x40.
2. The HE shall generate and track sequence numbers per unicast address.
3. HE-generated messages directed to broadcast or multicast addresses; i.e., where the I/G bit is set to 1, shall have a sequence number of 0 since this field is ignored by the NE for multicast and broadcast messages. Upon receiving a valid broadcast or multicast message from the HE, the NE shall not change the last received HE sequence number. The NE shall *always* process broadcast or multicast messages regardless of sequence number.
4. NE-originated transactions will have bit 6 of the MSGSEQ field set to 0. Thus, the range for the NE is 0x00 through 0x3F with wraparound to 0x00.
5. As a requestor, the NE can have only a single originating message requiring a response outstanding at any time (see Section 4.8). Thus, the NE only needs to track the sequence number for this single value.
6. The MSGSEQ field is incremented by the originator of the number. The sequence number shall be incremented only:
 - a. When a response is received with a matching sequence number (excluding the SYN bit, see Section 3.3.4.2); or
 - b. When a requestor's maximum allowed number of MAC layer transmission retries has been exceeded. The MSGSEQ shall not change if a message must be retransmitted at the MAC layer, which occurs only when a response or acknowledgement has not been received within a pre-determined timeout window, and the maximum allowed number of MAC layer transmission retries for this message has not been exceeded. See Section 4 of this specification for additional details on MAC protocol operation.

7. The responding entity shall save the sequence number of the last received message directed to its unicast address and perform one of the following:
 - a. If the MSGSEQ field is different from the last one seen, the responder should process the message, form a response if one is required, and send it. The responding entity shall take the value of the sequence number in the MSGSEQ field from the request and place it in the MSGSEQ field of its response.
 - b. If the MSGSEQ field is the same as the last one seen, the responder knows that its last response was not received and it should resend the response. The responder should *not* process the message again. It must simply resend the previously transmitted message. The responding entity shall take the value of the sequence number in the MSGSEQ field from the request and place it in the MSGSEQ field of its response.
8. If the responding entity has been reset, it shall process the first received message directed to its unicast address regardless of the value in the MSGSEQ field. *Note:* A possible implementation refinement to ensure subsequent message exchanges are synchronized is to initialize the “last sequence number” to an out-of-range value that a requestor cannot possibly support. This would guarantee that the first message from a responder after a reset always has a unique sequence number associated with it that forces the requestor to re-issue the original request thus ensuring message exchange re-synchronization.

3.3.4.2 SYN (Bit 7)

The following rules govern the selection of the SYN bit value and elicited behavior:

1. After a device (HE or NE) is reset, it shall set the SYN bit to 1 in every packet it originates and sends to a given responder until the first correct response is received from that responder. When the SYN bit is set to 1 by a requestor, the responder is not to verify the MSGSEQ field in the message. The MSGSEQ field contained within the packet is to be used by the requestor as the last received value. This will synchronize the responder to the current requestor sequence number.
2. The SYN bit shall always be set to 0 when responding to a request. When the SYN bit is set to 0 by a requestor, the responder is to verify the MSGSEQ field in the packet.

Section 4 of this specification provides additional information on the use of the Sequence field. It also includes a sample message exchange for illustration purposes.

3.3.5 Length

The Length field consists of two bytes and specifies the number of bytes in the payload field of the MAC layer packet. Although the *theoretical* maximum payload length is 65,535 bytes, the absolute maximum message length that may be transmitted (including all message overhead and Synch byte padding) will be determined by the maximum duration of return channel transmissions before automatic RF transmission cutoff is invoked. Document SCCTE 25- *HMS*

Outside Plant Status Monitoring – Physical (PHY) Layer Specification v1.0 requires that HMS-compliant transponders support automatic RF transmission cutoff on the return channel to shut down transponders that have failed with their transmitter ON.

An implementation of this protocol need not accept messages whose length exceeds 484 bytes. However, it is recommended that implementations support larger messages whenever feasible. Synch bytes inserted in the payload do *not* count towards the message length. See Section 3.4.3.

3.3.6 Payload

The payload field contains the data delivered to/from the higher layer protocols.

3.3.7 Frame Check Sequence (FCS)

The FCS field consists of two bytes. It is CCITT CRC-16 as documented in RFC 1662, appendices C.1 and C.2. The CRC calculation is performed over the entire packet, *excluding* the Synch field, but *including* the Control, Address, Sequence, Length, and Payload fields. Synch byte insertions for achieving transparent throughput of all data (see Section 3.4.3) are NOT included in the CRC calculation.

The final value obtained from the CRC calculation is complemented and transmitted *least significant byte first*. The following example illustrates this convention (sample forward path message, all values in HEX):

```
A5 00 00 10 3F 00 43 21 49 00 01 02 1D 1C
```

The FCS for this message is calculated to be 0xE3E2. When complemented, the value is 0x1C1D. This is then transmitted least significant byte first (0x1D, 0x1C).

3.4 MAC Packet Delimiters

The Synch, Control, Length and FCS fields are used to delimit a packet and indicate its integrity.

3.4.1 Packet Start

Detection of a Synch byte followed by a non-Synch byte will identify the start of a packet. Characters received after the end of a packet (see Section 3.4.2) but prior to detection of a new Synch byte and a non-Synch byte combination shall be discarded.

3.4.2 Packet End

The exact location of the FCS and the end of the packet can be calculated from the Length byte. The integrity of the packet is checked using the FCS. Packets with an invalid FCS shall be discarded. Packets with a valid FCS, but with invalid content will also be discarded.

3.4.3 Synch Byte Padding

In order to ensure message synchronization and obtain data transparency in the message, it is necessary to distinguish a true Synch byte from any other byte in the payload that has the same value. To accomplish this, a transmitting device (NE or HE) will insert the synch byte *after* any data byte having a value of 0xA5. This rule shall apply to the Address, Sequence, Length, Payload, and FCS fields but *not* to the Synch and Control fields. This ensures that the Synch byte and non-Synch byte combination will never be found together in the remainder of the packet.

After detection of the start of a packet, the receiver of the packet will remove one synch byte from any two-byte sequence that contains back-to-back synch bytes [0xA5, 0xA5]. If a single synch byte is detected within the packet, the data up to that point shall be discarded and the receiver shall begin the packet delimitation process again, using the newly received 0xA5 as the start of packet indicator.

Synch bytes added for data transparency are *not* counted toward the length of the packet, and are *not* included in the FCS calculation for a packet by either the sender or the receiver.

3.5 MAC Protocol Data Units (PDUs)

MAC PDUs are contained in the Payload field of the message. MAC PDU structure is illustrated in **Figure 6**.

Figure 6: MAC PDU Structure

Payload	Payload+1				Payload+n
CMD	Data	Data	Data	Data	Data

The presence of the Data fields depends on the PDU.

The PDUs defined for the MAC layer are listed in **Table 5**. Since all MAC layer messages are transaction-based, a list of possible transactions is shown in **Table 6**.

Table 5: MAC PDUs

PDU Name	CMD	Section
NAK	0x00	3.5.1
ACK	0x01	3.5.2
STATRQST	0x02	3.5.3
STATRESP	0x03	3.5.4
TALKRQST	0x04	3.5.5
TALK	0x05	3.5.6
CONTMODE	0x06	3.5.7
REG REQ	0x07	3.5.8
SET ADDR	0x08	3.5.9
REG END	0x09	3.5.10
CHNLDESC	0x0A	3.5.11
INVCMD	0x0B	3.5.12
TIME	0x0C	3.5.13

Table 6: Possible MAC Protocol Transactions

Originator	PDU	Responder	Possible Responses
HE	STATRQST	NE	STATRESP
HE	CONTMODE	NE	ACK or INVCMD
HE	TALK	NE	NAK REG_REQ INVCMD Non-MAC protocol message
HE	SET_ADDR	NE	ACK INVCMD
HE	REG_END	NE	ACK or INVCMD
HE	CHNLDESC	NE	ACK or INVCMD
HE	TIME	NE	ACK
NE	TALKRQST	HE	ACK

All of these MAC transactions can be processed by the NE before the NE is registered. The only message restriction at this time is that SNMP traps shall not be transmitted by the NE prior to registration completion as signaled by reception of a successful REG_END PDU from the HE (see Section 3.5.10). Additionally, there is no restriction on SNMP Get, GetNext, and Set requests.

3.5.1 NAK

The NAK PDU is a *possible* NE response to the HE TALK PDU. The NAK PDU has the format shown in **Table 7**. Description of the use of this message can be found in Appendix A, Section A.5.5.

Table 7: NAK PDU Format

Field	Size (bytes)	Value
CMD	1	0x00

3.5.2 ACK

The ACK PDU can be originated by the HE or the NE. The ACK PDU has the format shown in **Table 8**.

Table 8: ACK PDU Format

Field	Size (bytes)	Value
CMD	1	0x01

Only unicast addresses can be used with the ACK PDU. Additional details on the use of the ACK PDU can be found in Appendix A, Section A.5.5.

3.5.3 STATRQST

The STATRQST PDU is originated by the HE. The expected response is a STATRESP PDU. The STATRQST PDU has the format shown in **Table 9**.

Table 9: STATRQST PDU Format

Field	Size (bytes)	Value
CMD	1	0x02

Only unicast addresses can be used with the STATRQST PDU.

3.5.4 STATRESP

The STATRESP PDU is the NE response to a HE STATRQST PDU. The STATRESP PDU has the format shown in **Table 10**. The STATRESP PDU has a one-byte STATUS Data field associated with it. The STATUS Data field bit definition is shown in **Figure 7**.

Table 10: STATRESP PDU Format

Field	Size (bytes)	Value
CMD	1	0x03
STATUS	1	See Figure 7

Figure 7: STATRESP STATUS Byte – Bit Definition

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
RSVD3	RSVD2	RSVD1	MINOR	MAJOR	CNTCUR	CNTNRM	CHNLRQST

Note that this STATUS byte is *identical* to the commonNEStatus variable defined in document SCTE 38-3, *HMS Common Management Information Base*.

3.5.4.1 CHNLRQST (Bit 0)

The CHNLRQST bit indicates when the NE has unsolicited messages it wants to transmit to the HE. See **Table 11** for the bit value definitions. See **Figure 9** for the state diagram governing the actions and usage of contention.

Table 11: CHNLRQST Bit Settings

Value	Meaning
0	NE has no unsolicited messages to transmit.
1	NE has unsolicited messages that will be transmitted when the return channel is allocated a transmit opportunity with a TALK PDU, as permitted by the registration state.

Until a NE is registered, only a REG_REQ PDU can be generated (see Section 3.5.8). After successful registration (REG_END with SUCCESS status, see Section 3.5.10), the CHNLRQST bit shall be set for any non-MAC messages that are to be transmitted (e.g., SNMP Traps).

3.5.4.2 CNTNRM (Bit 1)

The CNTNRM bit indicates the “normal” state of contention, as set by the last CONTMODE PDU message (see Section 3.5.7). See **Table 12** for the bit value definitions.

Table 12: CNTNRM Bit Settings

Value	Meaning
0	The “normal” mode of contention is OFF for this NE.
1	The “normal” mode of contention is ON for this NE.

3.5.4.3 CNTCUR (Bit 2)

The CNTCUR bit indicates the “current” state of contention, as set by the last CONTMODE PDU message (see Section 3.5.7). See **Table 13** for the bit value definitions.

Table 13: CNTCUR Bit Settings

Value	Meaning
0	Contention is OFF for this NE.
1	Contention is ON for this NE.

3.5.4.4 MAJOR (Bit 3)

The MAJOR bit indicates whether alarms with a major severity are present in the NE or in the equipment monitored by the NE. See **Table 14** for the bit value definitions.

Table 14: MAJOR Bit Settings

Value	Meaning
0	No alarms with MAJOR severity are present.
1	Alarms with MAJOR severity are present.

3.5.4.5 MINOR (Bit 4)

The MINOR bit indicates whether alarms with a minor severity are present in the NE or in the equipment monitored by the NE. See **Table 15** for the bit value definitions.

Table 15: MINOR Bit Settings

Value	Meaning
0	No alarms with MINOR severity are present.
1	Alarms with MINOR severity are present.

3.5.4.6 RSVDx (Bit 7:5)

The bits identified as RSVD are reserved for future use. They must be set to 0.

3.5.5 TALKRQST

The TALKRQST PDU is originated by a NE. The expected HE response is the ACK PDU. The TALKRQST PDU has the format shown in **Table 16**.

Table 16: TALKRQST PDU Format

Field	Size (bytes)	Value
CMD	1	0x04

The TALKRQST is transmitted by the NE *only* under the following conditions:

1. The NE *must* have unsolicited messages that it wants to transmit.
2. Contention mode *must* be in the ON state for the NE ($C_c = 1$). See Section 3.5.7.

Once an ACK PDU response has been received, the TALKRQST PDU can be transmitted again in either of two cases:

1. The current contention mode of the NE has been toggled OFF then ON again using the CONTMODE PDU (effectively a new contention period, see Section 3.5.7). In this case, the TALKRQST PDU can be transmitted again since the CHNLRQST bit (Bit 0 in Status byte of the STATRESP PDU) is still set; or

2. The NE transmitted a NAK PDU in response to a TALK PDU; i.e., the last time the NE was given permission to transmit it had no more messages to send (see Section 3.5.6). In this case the NE, which previously had no more messages to transmit, now has new outstanding messages and is permitted to generate a new TALKRQST PDU.

3.5.6 TALK

The TALK PDU is originated by the HE. The expected NE responses are:

1. NAK PDU (no more messages to transmit).
2. Non-MAC protocol message (e.g., SNMP Trap over Serial).
3. REG_REQ PDU (NE requesting registration, see Section 3.5.8).

The TALK PDU has the format shown in **Table 17**. The TALK PDU has a one-byte ACKSEQ Data field associated with it.

Table 17: TALK PDU Format

Field	Size (bytes)	Value
CMD	1	0x05
ACKSEQ	1	See text

The TALK PDU gives the addressed NE access to the return channel to transmit a single message. In typical usage, the HE issues a CONTMODE PDU to turn off contention mode, then issues the TALK PDU to give the clear return channel to the NE. See the transaction example illustrated in **Table 20**.

The ACKSEQ field of the TALK PDU contains the sequence number of a previous message that *this* packet is acknowledging. In the situation where the HE has no previous message to acknowledge, the ACKSEQ field shall be 0xFF.

If the message sequence number in the ACKSEQ data field of the TALK PDU does not match the expected number, the NE shall respond with the INVCMD PDU using the “Invalid parameter” error code (see Section 3.5.12). The expected HE behavior would then be to re-issue a TALK PDU. The ACKSEQ byte in the TALK PDU will have a sequence number of 0xFF to indicate that the HE lost track of the sequence numbers. This will cause the NE to retransmit its last response to the HE TALK PDU allowing the HE to resynchronize correctly.

3.5.7 CONTMODE

The CONTMODE PDU is originated by the HE. The CONTMODE PDU has the format shown in **Table 18**. The CONTMODE PDU has two Data fields associated with it: the MODE field and the DURATION field both of which are one byte in length.

Table 18: CONTMODE PDU Format

Field	Size (bytes)	Value
CMD	1	0x06
MODE	1	See Table 19
DURATION	1	Time duration of $C_C = 1$

3.5.7.1 CONTMODE:MODE

The MODE field determines the contention state for the addressed NEs. The expected NE response to the CONTMODE PDU is an ACK PDU *only* if a unicast address is used and the MODE value is one of those in **Table 19** (even if the MODE value is not applicable). An INVCMD PDU response shall be transmitted if a unicast address is used and the mode value is *not* one of those shown in **Table 19**.

Table 19: CONTMODE:MODE Settings

Value	Meaning
0 (OFF)	Contention is turned OFF for the addressed NEs. $C_N = 0$, $C_C = 0$. DURATION has no effect.
1 (ON)	Contention is turned ON for the addressed NEs. $C_N = 1$, $C_C = 1$. DURATION is meaningful.
2 (INH)	Contention is <i>inhibited</i> for the addressed NEs. $C_N = \text{unchanged}$, $C_C = 0$. DURATION has no effect.
3 (RES)	Contention is <i>restored</i> for the addressed NEs. $C_N = \text{unchanged}$, $C_C = C_N$. DURATION is meaningful for NEs with $C_N = 1$.
4 (REG)	Contention is <i>enabled</i> for non-registered NEs. $C_N = 0$, $C_C = 1$. DURATION is meaningful for these NEs. Contention is <i>inhibited</i> for all registered NEs. $C_N = \text{unchanged}$, $C_C = 0$. DURATION has no effect for these NEs.

C_C : Contention mode “current” – the setting of this flag controls whether or not contention is currently enabled or disabled for the NE. A value of 0 means that the NE is *not* permitted to send the TALKRQST PDU.

C_N : Contention mode “normal” – the setting is restored with the MODE value of 3. This flag is changed *only* with the OFF and ON MODE values.

Upon NE power up for the first time or NE reset, the state of these flags shall be

$$C_N = 0, C_C = 0$$

Figure 9 in section 4.10.1 illustrates the applicable state machine diagrams and describes how these modes are to be used in the NE. If a MODE value is valid, but not applicable in a given state (as shown in the state diagram), it shall not be processed. However, if the NE was addressed using a unicast address it shall respond with an ACK PDU.

Table 20 illustrates the use of the CONTMODE PDU in the case of a NE with three messages to send. The value in parentheses for the TALK PDU is the value of the ACKSEQ field.

Table 20: NE Message Retrieval Example

HE	Message Sequence Number		To/From	NE	Message Sequence Number	MODE Value
CONTMODE ON	00	->	*			1
		<-	A	TALKRQST	15	1
ACK	15	->	A			1
CONTMODE INH	00	->	*			0
TALK (0xFF)	43	->	A			0
		<-	A	SNMP Trap 1	43	0
CONTMODE RES	00	->				1
		<-	A	¹ TALKRQST	16	1
ACK	16	->	A			1
TALK (0x43)	44	->	A			1
		<-	A	SNMP Trap 2	44	1
TALK (0x44)	45	->	A			1
		<-	A	SNMP Trap 3	45	1
TALK (0x45)	46	->	A			1
		<-	A	NAK	46	1
				<i>New alarm occurs</i>		1
		<-	A	² TALKRQST	17	1
ACK	17	->	A			

¹Case 1: New contention window

²Case 2: New alarms after a NAK, same contention window

3.5.7.2 CONTMODE:DURATION

When a CONTMODE PDU is issued which changes the state of C_C to 1, the DURATION field specifies the number of seconds that this mode will be active. Specifically, the DURATION field has meaning for the ON, RES, and REG modes. This field has *no meaning* when the state of C_C will be set to 0. Note that if a RES mode is issued and C_C is set to 0, the DURATION field, though valid, has no effect. A value of 0 in the DURATION field indicates unlimited time.

If the duration timer is active; i.e., a previous CONTMODE PDU with MODE setting and DURATION value has started the timer, and a new CONTMODE PDU with a new MODE setting and DURATION field is received, the timer is restarted using the new DURATION field value.

The duration timer acts as a “master shutoff” meaning that once the DURATION period expires a state change to $C_C = 0$ occurs. This action is identical to using all MAC layer transmission retries (see Section 4). When this occurs, the NE shall *not* transmit any further TALKRQST packets. Note that any CONTMODE PDU which explicitly sets $C_C = 0$ prior to the expiration of the DURATION period will have the same effect.

The DURATION field protects against the possibility of the HE transmitting a CONTMODE PDU setting $C_C = 0$ that is not received by the NE. In this case, the DURATION field and timer-

activated shutoff action provides a NE-based failsafe backup mechanism to prevent unwanted transmissions.

3.5.8 REG_REQ

The REG_REQ PDU can be generated by a NE in response to the TALK PDU. The REG_REQ PDU has the format shown in **Table 21**. The REG_REQ PDU has a four-byte IP_ADDRESS Data field associated with it.

Table 21: REG_REQ PDU Format

Field	Size (bytes)	Value
CMD	1	0x07
IP_ADDRESS	4	IP Address programmed into the NE (IPv4 only)

The NE transmits the REG_REQ *only* after it “boots” (power-up, hard or soft reset, etc.) The NE uses this message to register it in the system. This message may be transmitted *only* when the contention state is non-REG (see **Figure 9**). Note that if a REG_END PDU is received when this message is waiting to be transmitted, it will cause the NE to cancel the transmission of this message (see Section 3.5.10). See Section A.7 for more details about the Auto-Registration process.

3.5.9 SET_ADDR

The SET_ADDR PDU is originated by the HE. The expected NE response is the ACK PDU. The SET_ADDR PDU has the format shown in **Table 22**. The SET_ADDR PDU has a four-byte IP_ADDRESS Data field associated with it.

Table 22: SET_ADDR PDU Format

Field	Size (bytes)	Value
CMD	1	0x08
IP_ADDR	4	Appropriate

The HE transmits the SET_ADDR command to set the IP address of the NE. The value for IP_ADDR can be either:

1. Address 0.0.0.0 for a NE in a proxy system; or
2. A real IP address. How this IP address is determined or obtained by the HE is beyond the scope of this document. This could be the IP address received with the REG_REQ PDU; i.e., the HE is setting the NE to the IP address already programmed into the NE; or
3. The IP address of the HE (only in a proxy system).

The following ranges of IP addresses are reserved and define sets of invalid IP addresses for the NEs:

1. 224.0.0.0 – 239.255.255.255. This address range is reserved for IP multicast addresses (Class D); and
2. 240.0.0.0 – 255.255.255.255. This address range is reserved for future use (Class E).

The IP address of the NE must not be set within any of the above ranges.

Only unicast MAC addresses may be used with this command. The NE must discard a SET_ADDR command if a MAC multicast address or the MAC broadcast address is used. The NE shall respond with an INVCMD PDU if any of the following occurs:

1. If the NE was unable to set its IP address as indicated, the NE shall respond with an INVCMD PDU with the “Undefined error” value (see Section 3.5.12). Note that this does not imply anything about the validity of the IP address, but rather the ability of the NE to save the IP address in non-volatile memory; or
2. If the NE is commanded to set its IP address to an invalid IP address, the NE shall respond with an INVCMD PDU with the “Invalid parameter” value (see Section 3.5.12).

3.5.10 REG_END

The REG_END PDU is originated by the HE. The expected NE response is the ACK PDU. The REG_END PDU has the format shown in **Table 23**. The REG_END PDU has two data fields associated with it: a one-byte STATUS field and a four-byte TOD field.

Table 23: REG_END PDU Format

Field	Size (bytes)	Value
CMD	1	0x09
STATUS	1	See Table 24
TOD	4	Time of day in POSIX format, most significant byte first

3.5.10.1 REG_END:STATUS

The REG_END PDU is transmitted by the HE upon completion of NE registration. The STATUS field indicates NE registration status. Defined STATUS field settings are shown in **Table 24**.

Table 24: REG_END:STATUS Settings

Value	Meaning
0	SUCCESS. Registration succeeded. The NE shall continue its startup sequence.

1	DENIED. Registration has been denied. The NE may optionally use the CHNLDESC PDU mechanism (see Section 3.5.11) to search for another channel, or it may request registration on this channel again.
2	FAILED. Registration failed. The NE must wait until the next registration opportunity (CONTMODE REG).
3	PENDING. Registration is pending. The NE has found the correct HE but the HE is not yet ready to process this NE. The NE shall not send any further registration requests. The NE shall not send any SNMP Traps or perform alarm processing.

Receipt of the REG_END PDU with a STATUS value of 0 (SUCCESS) shall change the contention state to REG (see **Table 19** and **Figure 9**). Additionally, if the NE has a pending REG_REQ PDU waiting to be transmitted, receipt of the REG_END will clear this pending request.

The NE shall be permitted to send SNMP Traps and may perform alarm processing *only* upon receiving a STATUS of 0 (SUCCESS). If a REG_END PDU with STATUS of 3 (PENDING) is received by the NE, the NE must still wait for reception of a REG_END PDU message with STATUS of 0 (SUCCESS).

Upon reception of a REG_END PDU with a status of PENDING, the NE shall remain in that state for a maximum period of one hour. At the end of that time, if the NE is still in that state, it shall return to the non-registered OFF state.

Upon reception of a REG_END PDU with a status of SUCCESS, the NE shall not recognize any further REG_END PDU commands. If a unicast address was used, the transponder shall respond with an INVCMD PDU with the “Invalid parameter” error code (see Section 3.5.12).

3.5.10.2 REG_END:TOD

The TOD field shall contain the time in POSIX format (see Section A.2) with the most significant byte first. The NE is *required* to synchronize its internal time-of-day clock to this time. This field is always valid regardless of the value of the STATUS field.

3.5.11 CHNLDESC

The CHNLDESC PDU is originated by the HE. The expected NE response (unicast address only) is the ACK PDU. The CHNLDESC PDU has the format shown in **Table 25**. The CHNLDESC PDU has two Data fields associated with it: the FORWARD field and the RETURN field both of which are four bytes in length.

Table 25: CHNLDESC PDU Format

Field	Size (bytes)	Value
CMD	1	0x0A
FORWARD	4	Forward channel frequency in use for this channel (center frequency in Hz)

RETURN	4	Return channel frequency in use for this channel (center frequency in Hz)
--------	---	---

The CHNLDESC is transmitted by the HE under *any* of the following conditions:

1. Periodically, *at least* every 30 seconds, with a +5 second tolerance, using the broadcast address. This is used by the NE to automatically find the proper forward and return channels in use.
2. Anytime forward or return channel frequencies are changed. In this case, it is *recommended* that the message be transmitted several times in sequence. There are no address restrictions in this mode. If a unicast address is used, the NE must send an ACK PDU in response.

The NE shall *always* process this PDU if it belongs to the addressed group. If either of the frequencies specified in the PDU are invalid for the NE, then:

1. The NE shall *not* change either frequency; and
2. If a unicast address was used, the NE will reply with the INVCMD PDU using the “Invalid parameter” error code (see Section 3.5.12).

The NE shall implement a failsafe mechanism to recover from loss of forward channel frequency due to a requested frequency change. The recovery method used shall be determined by the vendor. The method used to determine loss of forward frequency shall also be determined by the vendor.

3.5.12 INVCMD

The INVCMD PDU can be originated by the NE in response to a command from the HE. This message is transmitted *only* if a unicast address was used in the original message. The INVCMD PDU has the format shown in **Table 26**. The INVCMD PDU has a one-byte REASON Data field associated with it.

Table 26: INVCMD PDU Format

Field	Size (bytes)	Value
CMD	1	0x0B
REASON	1	Reason code (see Table 27)

3.5.12.1 INVCMD:REASON

This message is transmitted by the NE with the REASON field indicating various error conditions. Defined REASON field codes are listed in **Table 27**.

Table 27: INVCMD:REASON Codes

Value	Meaning	Response To
0x00	Undefined error	CHNLDESC: Unable to execute* SET_ADDR: Unable to execute*
0x01	Invalid parameter	CHNLDESC: Invalid frequencies CONTMODE: Invalid MODE TALK: Invalid ACKSEQ number REG_END: Invalid STATUS SET_ADDR: Invalid IP address

*Parameters are valid but the transponder cannot execute the command for other reasons (e.g., non-volatile write did not succeed)

3.5.13 TIME

The TIME PDU is originated by the HE at its discretion. The expected NE response is an ACK PDU *only* if a unicast address is used. The TIME PDU has the format shown in **Table 28**. The TIME PDU has a four-byte TOD Data field associated with it.

Table 28: TIME PDU Format

Field	Size (bytes)	Value
CMD	1	0x0C
TOD	4	Time of day in POSIX format, most significant byte first

3.5.13.1 TIME:TOD

The TOD field shall contain the time in POSIX format (see Section A.2) with the most significant byte first. The NE is *required* to synchronize its internal time-of-day clock to this time.

4 MAC Protocol Operation

This section covers key operational characteristics to support the interaction between HMS-compliant transponders that interface to OSP NEs and a centralized HE. These procedures are critical to ensure interoperability among multiple NEs.

4.1 Non-Volatile Parameters

The parameters listed in **Table 29** *must* be stored in non-volatile memory for proper initialization of the NE after a power failure. Note that this list is not exhaustive; it simply gives the minimal parameters required for operation after a reset.

Table 29: Non-Volatile Parameters

Parameter
Forward channel frequency
Return channel frequency
Return channel power
MAC Address
IP Address
k parameter (to calculate backoff period before attempting a new transmission in contention mode, see Section 4.8.5)

The IP Address is inserted into the SNMP Trap message in the appropriate field.

4.2 Duplex Capabilities

All NEs shall support half-duplex operation. There is no requirement for full-duplex operation.

4.3 Packet Priorities

The MAC layer shall treat all packets with equal priority regardless of protocol. Both the HE and the NEs shall transmit packets on a first-in, first-out (FIFO) basis.

4.4 Packet Reception

The receiving device (NE or HE) looks for a proper Synch byte followed by a non-Synch byte combination to indicate the start of a packet. Data is discarded until a proper packet start is found. Once a proper packet start is identified, packet length is determined using the Length field, reception is completed and the FCS is calculated on the incoming data. The calculated FCS is compared to the transmitted FCS. If they match, the packet is declared valid and passed on to the appropriate higher layer protocol. If the calculated FCS does not match the transmitted FCS, the packet is discarded. If the FCS is valid, but subsequent decoding of the message shows invalid contents, the packet is discarded. Synch bytes added for data transparency are *not* counted toward the length of the packet, and are *not* included in the FCS calculation for a packet by either the sender or the receiver.

4.5 NE Responses

4.5.1 NE Processing Times – Broadcast and Multicast Messages

The NE shall *never* respond to any message containing a MAC address with the I/G Address Bit set to 1. This indicates either a multicast addresses or the broadcast address. However, if the contention state for the NE is turned ON as a result of such a message, the NE is permitted to send TALKRQST messages until the contention state is reset.

Processing times for messages received at the NE must conform to the following rules:

1. A NE must be able to process a packet 250 ms after reception of a MAC packet with the I/G Address Bit set to 1. See Section 3.3.3 for details about addresses.
2. A NE must be able to process a packet 5 s after reception of a SNMP packet with the I/G Address Bit set to 1.

4.5.2 NE Response Times – Unicast Messages

When a NE receives a MAC PDU management message (protocol identifier 0000) addressed to its unicast address and that requires a response, the NE shall begin to respond within 15 ms; i.e., transmit the first byte of its response. This interval begins following the receipt of a valid forward channel packet and ends when transmission of the response begins on the return channel.

If a NE does not respond to a MAC management message within 15 ms; i.e.: it times out, the HE can assume that the NE will not respond to this particular message. The HE may then initiate an error handling procedure which may attempt to contact the NE again or other NEs around it in the network, or it may invoke other such actions that the HE vendor deems appropriate.

Any time the NE receives a non-MAC PDU management message; i.e., a message with protocol identifier other than 0000, addressed to its MAC unicast address and that requires a response, the NE shall begin to respond within five seconds, i.e.: the timeout period shall be five seconds.

4.6 Message Sequence Numbers and Transaction Synchronization

The HMS MAC protocol is transaction-based; i.e., every originating message from a “requestor” has a corresponding response from the “responder” regardless of which device originated the message. The Sequence field in all HMS MAC packet headers consists of a single byte and defines a message sequence number to ensure message exchanges are synchronized. In order to handle possible loss of messages in either the forward or the return channel, and to avoid duplication of messages at the application layer, all messages have a sequence number. The Sequence field in all HMS MAC packet headers and the rules governing its use are described in detail in Section 3.3.4.

In addition, this HMS MAC specification also defines a one-byte ACKSEQ Data field associated with the MAC TALK PDU (see Section 3.5.6). The ACKSEQ field in the TALK PDU identifies

the sequence number of a previous message that *this* packet is acknowledging. The HE uses the TALK PDU to give the addressed NE access to the return channel to transmit a single message while also acknowledging reception of the previous message the NE transmitted.

Table 30 illustrates an example of the usage of the Sequence field in the HMS MAC packet headers and the ACKSEQ Data field associated with the MAC TALK PDU. The Event column is for reference only. The value in parentheses for the TALK PDU is the value of the ACKSEQ field.

Table 30: MAC Sequence Field Example (Non-Contention Mode)

Event	HE	Message Sequence Number		NE	Message Sequence Number
1	STATRQST	x40	->		
2			<-	STATRESP CHNLRQST = 1	x40
3	⁴ TALK (0xFF)	x41	->		
4			<-	SNMP Trap 1	x41
5	¹ TALK (0x41)	x42	->		
6			<-	¹ SNMP Trap 2	x42
7	² TALK (0x42)	x43	->	<i>Forward path message lost</i>	
8	² Timeout				
9	² TALK (0x42)	x43	->		
10			<-	SNMP Trap 3	x43
11	TALK (0x43)	x44	->		
12	³ Return path message lost		<-	SNMP Trap 4	x44
13	³ Timeout				
14	³ TALK (0x43)	x44	->		
15			<-	SNMP Trap 4	x44
16	TALK (0x44)	x45	->		
17			<-	NAK	x45

¹Normal case: The sequence number is different from the last one seen, so the NE will increment its internal pointer to the next message to be transmitted.

²The NE did not see this message at all, so the transaction does not complete. The HE must retransmit its message using the same sequence number.

³The Trap was lost in the return path. The HE times out, but does not know which message (forward path or the return path) was lost. Retry of the TALK is required. The NE will see that the sequence number is the same as the last one, so it will simply resend its last message.

⁴The HE has no previous message to acknowledge, so the value of the ACKSEQ field is 0xFF

4.7 Solicited Messages

Solicited messages are packets that are sent in response to a HE query. The HE does not transmit an ACK PDU in response to these packets.

4.8 Autonomous (Unsolicited) Messages

Autonomous, or unsolicited messages, are packets that are generated automatically by the NE; e.g., the result of an unexpected alarm condition occurring at the NE. A NE must signal the HE with the TALKRQST PDU when the NE Contention state is ON ($C_c = 1$). Only the TALKRQST PDU is permitted when the NE Contention state is ON and no alarm information is transmitted since delivery to the HE is not guaranteed (collisions may occur). The HE must send an ACK message back to the NE when it receives a TALKRQST PDU. Only a single packet requiring an ACK response may be outstanding at the NE at any time. Retry packets are retransmissions of previously sent autonomous messages for which an ACK PDU was not received. Sections 4.8.1 through 4.8.7 describe how autonomous messages and collisions are handled in this MAC.

4.8.1 NE Contention State

Each NE has a Contention state (C_c). The Contention state indicates the following:

1. Contention state is ON: The NE is permitted to transmit unsolicited messages on the return channel.
2. Contention state is OFF: The NE may transmit only solicited messages. It cannot transmit unsolicited messages.

At NE boot, the NE Contention state is initialized to OFF.

The Contention state for a NE is determined by:

1. The address used to access this NE (unicast, multicast, or broadcast); and
2. The value of the MODE field in the CONTMODE PDU that addressed this NE. Refer to Section 3.5.7.

The contention state setting is persistent across forward path transmissions. See **Table 31**.

Table 31: Contention State Settings versus Forward Channel Packets

Forward Path Message	Address	CONTMODE MODE Value	NE Contention State C _c		
			NE X	NE Y	NE Z
1	Broadcast	0 (off)	OFF	OFF	OFF
2	Unicast X	0 (off)	OFF	OFF	OFF
3	Unicast X	1 (on)	ON	OFF	OFF
4	Unicast Y	0 (off)	ON	OFF	OFF
5	Unicast Y	1 (on)	ON	ON	OFF
5	Multicast (X,Y)	0 (off)	OFF	OFF	OFF
6	Multicast (Y,Z)	1 (on)	OFF	ON	ON
7	Broadcast	2 (inh)	OFF	OFF	OFF
8	Broadcast	3 (res)	OFF	ON	ON
9	Multicast (X,Y)	1 (on)	ON	ON	ON
10	Multicast (Y,Z)	0 (off)	ON	OFF	OFF
11	Broadcast	1 (on)	ON	ON	ON
12	Broadcast	0 (off)	OFF	OFF	OFF

ON – The NE is permitted to send any unsolicited messages it has for any protocol.

OFF – The NE is NOT permitted to send any unsolicited messages.

4.8.2 Collisions

A collision is defined as multiple unsolicited messages from different NEs arriving at the HE receiver simultaneously such that none of the messages is received properly. True collisions should occur only during a period when multiple NEs on the same return path have the Contention State ON. It is also possible that improper reception of an unsolicited message from the NE is a result of message corruption during transmission due to noisy conditions in the return channel such as ingress or impulse noise. Although message corruption in the latter case is not a direct result of a collision, both conditions will force re-transmission of the corrupted message.

4.8.3 HE Collision Detection

The HE may declare a collision. How this is done is at the vendor's discretion. This specification does not describe what a HE should do in the event of a collision. However, the following collision detection techniques are possible:

1. Received Signal Strength Indication (RSSI) higher than “normal.” Since the arriving return channel packets have a variable size and arrival time, the HE may utilize a power detector on a receiver to roughly detect the beginning and the end of the received packet on the return channel;
2. Bytes not received in time (inter-byte gaps), or entire packet not received in time;
3. Framing errors;
4. Improper protocol; and
5. Invalid FCS.

4.8.4 NE Collision Indication

The HE must respond with an ACK message to all return channel packets that require it within a predetermined timeout period. Currently, only the TALKRQST PDU requires an ACK. Collisions on the return channel are indicated to the originating NEs by the *lack* of the required ACK message from the HE because no specific indication of a collision is provided at the MAC layer.

The non-receipt of the HE ACK message within the timeout period indicates to the NE that something; e.g., a collision, excessive ingress noise, or other unknown condition, has prevented the proper reception of the return channel packet at the HE, and the NE must retransmit the message (see Section 4.8.5). This collision detection mechanism is part of the general technique known as ALOHA to support multiple user access to a common transmission channel.

4.8.5 Backoff Algorithm

The “Backoff” state is defined as the contention state when $C_C = 1$ and the NE is waiting for a random delay period Y to elapse, after which it will attempt to send a message again. The backoff or random delay Y is calculated using the following formula:

$Y = \text{random}[1, 2^k] * \text{BackoffPeriod}$, where

Y = Period of time to wait in ms (backoff)

k = 0 to 15 (default value of 6, default maximum is 15, absolute maximum is 15)

$\text{random}[]$ = Random number in range of 1 to 2^k

BackoffPeriod = Variable in milliseconds for *incremental* backoff time to wait. Default value is 6 ms, for a maximum backoff Y of approximately 197 seconds.

4.8.6 Backoff State Machine Description

When the NE has a packet to be transmitted *for the first time* when $C_C = 1$, the NE must first enter the “Backoff” state. For this first backoff, the initial value of k currently set is used (default value is 6). When the calculated backoff period Y has elapsed, the NE may then send the packet.

After the NE sends a packet requiring an ACK, the NE waits for the ACK PDU from the HE to determine if the transmission was successful. If the NE receives the ACK PDU within the predetermined timeout period following the transmission of the reverse channel packet, it declares a successful transmission and discards the successful packet.

Note that if the packet was successfully transmitted without a collision, then the HE received the packet *while* it was being transmitted. Therefore, the time required to receive the required ACK

packet is equal to [processing time of the HE] + [time required to transmit ACK packet] + [propagation delay].

If the transmission was not successful, as indicated by non-receipt of the ACK packet within the timeout period, the NE will delay for a new backoff period Y . In this case, the NE increments k by 1 (increasing the random number range by a factor of 2) to a maximum of 15 (or the value currently set in SCTE 38-3, *HMS Common Management Information Base*), calculates a new backoff period Y , enters the “Backoff” state again until period Y expires, then retransmits the packet. It then waits again to see if the retransmitted packet reaches the HE successfully (confirmed by reception of the ACK PDU within the timeout period). This process continues until any of the following conditions occur:

1. An ACK PDU is received for this packet (indicating the packet was received successfully); or
2. The maximum allowed number of MAC layer transmission retries is exceeded; or
3. C_C is set to 0.

After the maximum allowed number of MAC layer transmission retries has been exceeded, the NE gives up this attempt and no further transmissions are permitted until a backoff reset occurs (see Section 4.8.7). When the backoff state machine is reset, the NE may attempt to send this packet again.

If the correct ACK PDU is received late during the “Backoff” state the ACK is accepted and it is assumed that the original packet was received successfully.

If C_C is explicitly set to 0 by a new CONTMODE message or after expiration of the duration timer (see Section 3.5.7), then retries are cancelled. This also resets the backoff state machine to its initial starting point.

IMPORTANT NOTE

Although the term “random” has been used in this section, it is recognized that it is extremely difficult to implement a true random number generator. Because of this difficulty, it is incumbent upon the vendors of OSP monitoring equipment to implement the best possible pseudo-random number generator available. This specification cannot and does not dictate how this pseudo-random number generator works.

4.8.7 Backoff Reset

The backoff state machine is reset in the NE upon any of the following conditions:

1. When the NE has a new/different packet to be transmitted for the first time when $C_C = 1$;
or
2. Upon expiration of the duration timer (see Section 3.5.7); or

3. Upon receipt of any CONTMODE PDU; or
4. When the NE responds with a NAK PDU in response to a TALK PDU.

The resetting of the backoff state machine includes the timers and other logic in use for the transmission of unsolicited messages and implementation of the backoff algorithm. The resetting of the state machine permits the NE to attempt to resend a message that had previously failed due to exceeding the allowed MAC layer transmission retry limit.

4.8.8 Parameters

The parameters controlling autonomous message transmission for the HMS MAC layer are defined explicitly in **Table 32**. See also the latest revision of document SCTE HMS COMMON MIB, *HMS Common Management Information Base*.

Table 32: Backoff State Machine Parameters

Parameter Name	Description	Value
AckTimeout	Time that NE waits for a HE ACK message after completing a return channel packet transmission	15 ms (HE processing time) + 3 ms (time to transmit ACK message) + 1 ms (propagation delay) Default: 19 ms
BackoffPeriod	Basic unit of time that NE waits after <i>not</i> receiving an HE ACK message prior to message re-transmission	6 ms (see Section 4.8.5)
k	Controls the size of the random number window	Default value: 6 Absolute maximum value: 15 Default maximum value: 15
MaxMACLayerRetries	Number of times the NE will attempt to transmit its autonomous message	This parameter shall default to a value of 16
Y	Backoff time resulting from backoff algorithm calculation	Calculated

4.9 Return Channel Transmissions

There are two times when a NE is permitted to transmit:

1. Contention state in the NE is OFF

The NE may transmit a *single* return channel packet any time following the reception of a valid forward channel packet requiring NE response until NE access is turned OFF by a subsequent packet that disables its access. For example, a forward channel packet addressing a different NE. See **Figure 8**.

Figure 8: Return Channel Transmission Permitted

2. Contention state in the NE is ON

The NE may transmit a return channel packet any time following the reception of a valid CONTMODE PDU that turns the Contention state ON in the NE until its access is turned OFF by either a subsequent CONTMODE PDU that disables its access, or expiration of the duration timer for $C_C = 1$ (as set by the CONTMODE PDU). Note that return channel packet transmission in this case must follow the rules of contention and backoff.

4.10 MAC State Machines

The NE shall implement the state diagrams included in this section.

4.10.1 Contention State Machine

Figure 9 illustrates the state diagram for the contention state machine.

Figure 9: Contention State Diagram

4.10.2 Backoff State Machine

Figure 10 illustrates the state diagram for the backoff state machine.

Figure 10: Backoff State Diagram

Appendix A. Operational Details

A.1 Introduction

This appendix addresses various operational aspects concerning implementation of the HMS MAC protocol. Neither the main section of these specifications nor RFC 1157, A Simple Network Management Protocol (SNMP), specifically addresses these issues.

A.2 Time Of Day

The NE is required to maintain a time of day clock so that alarms may be time-stamped. However, the NE is not required to have a real-time hardware clock. After NE power-up, the clock shall begin at 0 (midnight January 1, 1970) and will maintain time from there until the time is synchronized by the management system. Vendors shall specify the accuracy for their clock. A resolution of 1 second is required. The drift of the clock (unsynchronized) shall be no more than 30 seconds over a 24-hour period.

A.2.1 Integer Representation

Any MIB variable specifying time in an Integer format will use the POSIX standard format of the number of seconds since January 1, 1970 and requires a 32-bit integer at a minimum. See also document SCTE HMS COMMON MIB, *HMS Common Management Information Base*.

A.3 Firmware Downloads

Remote NE firmware downloads; i.e., downloads performed over the RF serial link, shall be accomplished via SNMP. The exact mechanism is detailed in document SCTE HMS DOWNLOAD MIB, *HMS Transponder Firmware Download Management Information Base*.

A.4 NE Addressing

Each NE is assigned a unique IEEE MAC address as specified in Section 3.3.3 of this document. However, for addressing the NE in a system, two approaches are possible. Neither has any effect on the NE since the NE responds only to MAC addresses.

A.4.1 Direct Addressing Using Individual IP Address

Element Management Systems (EMSs) that support assignment of individual IP addresses to each NE within a MAC layer domain may find this a suitable approach. A unique IP address is assigned to each NE through the registration mechanism. The NE may then be addressed directly by IP address with the HE acting as a router or bridge.

SNMP Trap messages with NE alarms will have the IP address of the NE in the Trap. The NE is not required to have a full IP protocol stack, however this specification does provide for a mechanism to support such implementations (see Section 3.3.2).

A.4.2 Proxy Addressing Using Common IP Address

EMSS that assign a common IP addresses to support communications to all NEs within a MAC layer domain may find this a suitable approach. A common IP address is used to channel all communications between a HE and multiple NEs. Assignment and management of individual IP addresses for each NE is not required.

The HE serves as an SNMP proxy agent for the NEs. All SNMP messages sent to the HE contain the MAC address of the NE in the community string of the SNMP PDU. The format of this string does not matter as long as it uniquely identifies the NE to the HE. A recommended format for identifying a NE with MAC address 12-34-56-78-9A-BC is “123456789ABC”. The HE then performs a lookup function in an internal database using this community string to find the NE MAC address and sends the new SNMP PDU to the NE that was identified.

The community string has a maximum size of 64 bytes. See also document SCTE HMS COMMON MIB, *HMS Common Management Information Base*. A NE shall ignore the community string in SNMP packets it receives. The NE shall set the SNMP packet community string for the GetResponse PDU to the same value it received for the originating PDU; i.e., a GetRequest PDU.

A.5 Alarm Processing HMS MAC Protocol

A.5.1 Managed Parameter Properties

Document SCTE HMS PROPERTY MIB, *HMS Alarm Property Management Information Base* defines the properties that may be associated with each managed NE parameter. The properties defined in the SCTE HMS PROPERTY MIB can be applied to *any* parameter because the index to the MIB is the object identifier of the parameter. See **Figure 11**. In this example, the property analogAlarmLO is associated with managed NE parameter psOutputVoltage.

Figure 11: SCTE HMS Property MIB Usage

It is up to the vendor to indicate which properties apply to any given parameter. See **Table 33** for a list of properties that can be applied. For example, analog properties need not apply to a digital parameter (e.g., tamper switch).

Note

NE vendors may, at their discretion, support *additional* properties for parameters through a vendor-specific property MIB. This specification *recommends* that the same mechanism described here be used to associate the additional properties with each managed NE parameter.

Table 33: HMS Properties

Property Name	Description
LOLO	Alarm threshold for the extreme low condition
LO	Alarm threshold for the low condition
HI	Alarm threshold for the high condition
HIHI	Alarm threshold for the extreme high condition
Deadband	Deadband that applies to all alarm thresholds. After an alarm occurs, the parameter value must pass back over the alarm threshold by this amount for the alarm to be cleared.
Alarm Enable	Permits enabling and disabling of specific alarms: Bit 0: LOLO alarm Bit 1: LO alarm Bit 2: HI alarm Bit 3: HIHI alarm Bit 4: Reserved Bit 5: Reserved Bit 6: Reserved Bit 7: Reserved

Note: Nothing in this specification implies the severity of any particular alarm. See document SCTE HMS PROPERTY MIB, *HMS Alarm Property Management Information Base* for complete details about each field.

The thresholds and the deadband for any parameter must be of the same precision as the parameter. For example, if battery voltage is presented in units of 0.01VDC, then the thresholds and deadband must also be presented in units of 0.01VDC.

A.5.2 Alarm Thresholds and Operation

In the event that an alarm condition is detected, the alarm thresholds function as follows:

1. LOLO: When a parameter value crosses this threshold (value < threshold), the alarm will be indicated. The parameter returns from alarm when (value > threshold + deadband).
2. LO: When a parameter value crosses this threshold (value < threshold), the alarm will be indicated. The parameter returns from alarm when (value > threshold + deadband).

Note

Note: If a parameter value crosses directly to the LOLO alarm state, a LO alarm should not be triggered. For example, consider a parameter having LOLO and LO thresholds of 5 and 10 respectively and a deadband of 1. The parameter value is quiescent at a value of 15. Suddenly, the value drops to 2 with no intermediate values sensed. In this case, *only* the LOLO alarm should be triggered. If the value subsequently rises to a value of 7, the LO alarm should then be triggered. Conversely, if a LO alarm occurs first and the value progresses over the LOLO alarm threshold, that alarm should then be triggered.

3. HI: When a parameter value crosses this threshold (value > threshold), the alarm will be indicated. The parameter returns from alarm when (value < threshold - deadband).
4. HIII: When a parameter value crosses this threshold (value > threshold), the alarm will be indicated. The parameter returns from alarm when (value < threshold - deadband). Just as in the case of LO and LOLO, an excursion past the HI threshold directly to the HIII alarm level will cause only a HIII alarm.

Only one alarm state shall be active at any time. In the note above for the LO alarm, only the LO or the LOLO alarm is active and not both at the same time. In all cases, disabling the alarm *while* the alarm is active shall generate the following actions:

1. The alarm is reset to the nominal state and a trap is issued;
2. The alarm is deleted from the current alarm table; and
3. The alarm *remains* in the alarm log table (this is a history table).

A.5.3 Alarms MIB Information

Document SCTE HMS ALARMS MIB, *HMS Alarms Management Information Based*, is simple and provides for organized and effective alarm retrieval. The contents of the NE alarm list are defined and transferred as an octet string containing all of the recorded information for a particular alarm. This permits the efficient retrieval of *all* the information for a given alarm. The alarm list acts as a simple circular first in first out (FIFO), wrapping around and overwriting alarms in the list. Alarms are not removed from the list.

A.5.4 NE Alarm Processing

The NE shall not send any SNMP traps or perform alarm processing (detection, etc.) until a REG_END PDU is received with STATUS of 0 (SUCCESS). At that time, alarm processing is governed by the commonAlarmDetectionControl variable as defined in document SCTE HMS COMMON MIB, *HMS Common Management Information Base* as well as all other applicable MIB variables. Upon detecting an event, the NE stores it in an internal list for transmission later. Alarm notification and retrieval mechanisms and relevant examples are described in Section A.5.5.

A.5.5 Alarm Notification and Retrieval

The MAC layer provides a “notify and gather” mechanism where the HE is notified that a NE wants to transmit unsolicited messages. The HE can retrieve these messages by permitting the NE to send the messages reliably in a non-contention environment. The HE may then forward these messages via SNMP Trap mechanism to a higher layer EMS or cache them. Note that there is no requirement to perform message retrieval in a contention-free environment; however, that method is recommended.

There are two methods for determining that a NE has alarms to be transferred. These are described in the sections A.5.5.1 and A.5.5.2.

A.5.5.1 Notification – Polled Mode

The STATRESP PDU serves as the message *notification* mechanism via the CHNLRQST bit (see Section 3.5.4). In a strictly poll-based implementation of the HMS MAC protocol, the STATRQST/STATRESP transaction supports background polling and alarm notification. When the HE receives a STATRESP PDU message from a NE with the CHNLRQST bit in the STATUS field set to 1, it should add this NE to a list of NEs requesting permission to transmit unsolicited messages and process this list at its convenience. If the list is empty, the NE can be processed immediately; i.e.: it can be granted immediate access to the return channel to transmit a single message.

A.5.5.2 Notification – Contention Mode

The TALKRQST PDU originated from a NE serves as the message notification mechanism when contention mode is in the ON state (see Section 3.5.5). When the HE receives a TALKRQST PDU message, it must respond with the ACK PDU to signal the NE that the message has been received and that no additional TALKRQST PDU is necessary. Only the TALKRQST PDU is permitted when the NE contention state is ON (see Section 4.8) and no alarm information is transmitted until after the HE explicitly grants the NE access to the return channel.

A.5.5.3 Retrieval

To retrieve unsolicited messages from a NE, the HE can at its discretion first ensure that return channel contention is turned OFF for all NEs within the particular MAC layer domain through generation of the CONTMODE PDU with MODE value of OFF or INH (see Section 3.5.7). Following this, the HE must:

1. Transmit a TALK PDU to the NE to grant it immediate access to the return channel for transmission of a single message (packet);
2. Process the received packet from the NE. Typically, this packet will be of protocol type SNMP Trap Over Serial; and
3. Repeat sequence 1 and 2 at its discretion until the NE has no more messages to send. At this point, the NE response to the HE TALK PDU is a NAK PDU. Note that steps 1 and 2 constitute a single HMS MAC protocol transaction.

This specification does not state in what order the NE alarms should be sent. However, for consistency, it is *highly* recommended that the alarms be transmitted in the order in which they occurred. See the Section A.5.3 for additional detail on alarm retrieval during alarm overflow situations.

A.5.5.4 Alarm and Message Flows

Table 34 illustrates the expected message flow between HE and NE in a poll-based implementation of the HMS MAC protocol. In this instance, HE reception of a STATRESP PDU message with the CHNLRQST bit in the STATUS field set to 1 signals the HE that the NE has one or more messages to transmit. The HE immediately grants the NE access to the return channel via the TALK PDU to transmit a single message at a time until the NE generates a NAK PDU in response to the HE TALK PDU to signal it no longer has any outstanding messages to transmit. The value in parentheses for the TALK PDU is the value of the ACKSEQ field.

Table 35 illustrates the potential message flow between HE and NE in a contention-based implementation of the HMS MAC protocol. This example assumes contention has been enabled on the return channel and one or multiple NEs signals the HE via the TALKRQST PDU that it has one or more messages to transmit. The HE acknowledges each TALKRQST PDU via an ACK PDU back to each of the NEs.

Note in **Table 35** that for NEs B and C, even though initial transmissions over the return channel result in a collision, the TALKRQST PDUs are successfully transmitted after invoking the HMS MAC backoff and retransmission algorithm (see Section 4.8). Following transmission of ACK PDUs, the HE in this example turns return channel contention OFF via the CONTMODE PDU first. It then grants each NE access to the return channel via the TALK PDU to transmit a single message at a time until the NE generates a NAK PDU in response to the HE TALK PDU to signal it no longer has any outstanding messages to transmit. The process continues until all outstanding NE transmissions have been completed.

Table 34: Alarm Notification and Retrieval – Polled Mode

HE	Message Sequence Number		To/From	NE	Message Sequence Number	CHNLRQST Bit	Contention
STATRQST	41	->	A			0	0
		<-	A	STATRESP	41	0	0
				<i>Alarm detected</i>		1	0
STATRQST	42	->	A			1	0
		<-	A	¹ STATRESP CHNLRQST = 1	42	1	0
TALK (0xFF)	43	->	A			1	0
		<-	A	² SNMP Trap	43	1	0
TALK (0x43)	44	->	A			1	0
		<-	A	² SNMP Trap	44	1	0
TALK (0x44)	45	->	A			0	0
		<-	A	³ NAK	45	0	0

¹Notification

²The HE is simply giving *permission* for the NE to transmit uninterrupted. The actual message could be *any* protocol.

³This is used to indicate that the NE has no more messages to be transmitted.

Table 35: Alarm Notification and Retrieval – Contention Mode

HE	Message Sequence Number		To/From	NE	Message Sequence Number	CHNLRQST Bit	Contention
CONTMODE ON	0	->	*			0	1
		<-	A	¹ TALKRQST	15	A=1	1
ACK	15	->	A			A=1	1
		<-	B	¹ TALKRQST	25	A,B,C=1	1
		<-	C	¹ TALKRQST	35	A,B,C=1	1
B & C collide, backoff						A,B,C=1	1
Time passes						A,B,C=1	1
		<-	B	¹ TALKRQST	25	A,B,C=1	1
ACK	25	->	B			A,B,C=1	1
		<-	C	¹ TALKRQST	35	A,B,C=1	1
ACK	35	->	C			A,B,C=1	1
CONTMODE OFF	0	->	*	Disables contention for this return path		A,B,C=1	0
TALK(0xFF)	43	->	A			A,B,C=1	0
		<-	A	² SNMP Trap	43	A,B,C=1	0
TALK(0x43)	44	->	A			A,B,C=1	0
(message garbled)		<-	A	² SNMP Trap	44	A,B,C=1	0
Timeout occurs						A,B,C=1	0
TALK (0x43)	44	->	A	<i>Retry</i>		A,B,C=1	0
		<-	A	² SNMP Trap	44	A,B,C=1	0
TALK (0x44)	45	->	A			A,B,C=1	0
		<-	A	² SNMP Trap	45	A,B,C=1	0
TALK (0x45)	46	->	A	A has no more alarms to send		A=0 B,C=1	0
		<-	A	³ NAK	46	B,C=1	0
Repeat sequence			B			B,C=1	0

¹Notification

²The HE is simply giving *permission* for the NE to transmit uninterrupted. The actual message could be *any* protocol.

³This is used to indicate that the NE has no more messages to be transmitted.

A.6 Automatic Channel Discovery

This version (1.0) of the HMS MAC protocol defines a CHNLDESC PDU (see Section 3.5.11) that the HE originates to communicate forward and return channel frequencies in use to the NE. This can support optional implementation of an automatic channel discovery feature in the NE. At the vendor's discretion, the NE may be configured to automatically search for the forward and return channel frequencies currently in use. Since the HE is required to periodically transmit the CHNLDESC PDU, the following mechanism is suggested:

1. The NE starts by choosing a forward path channel and monitors it for valid forward path messages over a pre-determined time interval. This document does *not* specify how a forward channel may be chosen or how long a NE must stay tuned to a particular forward channel.
2. Once the NE has found a forward path channel with valid MAC messages, it listens for the CHNLDESC PDU for up to 35 seconds. If no PDU is heard, the NE may move onto a different forward path channel at its discretion. This document does not specify how another forward channel may be chosen.
3. After hearing a CHNLDESC PDU with valid forward and return channel frequencies, the NE should tune its return path transmitter to the frequency specified and attempt the Auto-Registration procedure described in section A.7.
4. If the Auto-Registration procedure fails, the NE may attempt to try another valid forward path channel at its discretion. This document does not specify what the NE should do.

A.7 Auto-Registration

This version (1.0) of the HMS MAC protocol requires that NEs register with the HE and provides the procedure and mechanisms to perform this function. Following NE reboot either by power-up, watchdog reset, commanded reset, manual reset, or other method, it shall perform any required internal initialization. After internal initialization is complete, the NE *may* use an Automatic Channel Discovery mechanism similar to the one described in section A.6 to search for the forward and return channel frequencies currently in use. Alternatively, the NE may use frequencies already provisioned.

Once the NE has found a valid set of frequencies, it requests registration. The following sequence and the example in **Table 36** illustrate a *potential* implementation of the auto-registration process:

1. The HE periodically transmits a CONTMODE PDU with MODE value of 4 (REG). Only those NEs that are *not* yet registered may respond.
2. The NE indicates it has messages to transmit by transmitting a TALKRQST PDU.
3. The HE transmits an ACK PDU to indicate to the NE that its TALKRQST PDU was received.

4. The HE eventually transmits a CONTMODE PDU with MODE value of INH to turn off registration requests.
5. The HE eventually transmits a TALK PDU to the NE.
6. The NE transmits a REG_REQ message with the IP address of the NE as it is currently configured. Refer to Section 3.5.8 of this specification.
7. The HE transmits a TALK PDU to the NE with the sequence number of the transaction in steps 5 and 6. The NE responds with a NAK indicating no more messages.
8. The HE determines the correct IP address for the NE. How the correct IP address is determined is beyond the scope of this document.
9. Optionally, the HE transmits a SET_ADDR PDU to the NE with the correct IP address. The NE transmits an ACK PDU back to the HE upon successful processing of the SET_ADDR PDU. Refer to Section 3.5.9 of this specification. Note that this transaction is not required if the HE determines that the NE is already configured.
10. The HE transmits a REG_END PDU with the appropriate status value (SUCCESS, DENIED, FAILED, or PENDING). The NE responds with an ACK PDU. Refer to Section 3.5.10 of this specification.
11. If the NE registration request was denied, the NE may opt to use the CHNLDESC PDU mechanism to search for another channel, or it may request registration on the current return channel again. If the registration request failed, the NE must wait until the next registration opportunity. If the registration request is pending, the NE shall not send any further registration requests. *The NE shall not send any SNMP Traps or perform alarm processing (detection, etc.) until a REG_END PDU is received with STATUS of 0 (SUCCESS).*
12. The HE restores the contention mode of the system using the CONTMODE PDU with MODE value of RES.
13. If the HE wants the contention mode of the NE turned ON, the HE transmits the CONTMODE PDU with MODE value of ON to the NE. This should be done using the unicast address of the NE. The NE shall respond with an ACK PDU.
14. When ready, the NE shall generate a SNMP trap. The mechanisms described in Section A.5.5 must be implemented for alarm notification and retrieval. *No SNMP Traps are permitted until the REG_END transaction is completed.*
15. The HE performs any other configuration required by the NE.

Table 36: Auto-Registration Implementation Example

HE	Message Sequence Number		To/From	NE	Message Sequence Number	CHNLRQST Bit	Contention
CONTMODE REG	00	->	*			0	1
		<-	A	¹ TALKRQST	1	1	1
ACK	1	->	A			1	1
CONTMODE INH ¹		->	*			1	0
TALK (0xFF)	42	->	A			1	0
		<-	A	REG_REQ	42	0	0
TALK (0x42)	43	->	A			0	0
		<-	A	NAK	43	0	0
SET_ADDR	44	->	A			0	0
		<-	A	ACK	44	0	0
REG_END (0)	45	->	A			0	0
		<-	A	ACK	45	0	0
CONTMODE RES	00	->	*				
CONTMODE ON ²	46	->	A				
		<-	A	ACK	46		

¹This is required to turn OFF the registration contention mode.

²This transaction is optional and it depends on whether the HE wants the NE in contention mode or not.

A.8 Configuration Changes and SNMP Trap Generation

The NE must be capable of recognizing configuration changes and notifying the upstream EMS of this event. To accomplish this, the NE shall maintain a check code value of 32 bits in size. See also SNMP commonCheckCode variable definition in document SCTE HMS COMMON MIB, *HMS Common Management Information Base*. The algorithm and data used to calculate this check code is vendor-specific. One suggested approach is CCITT CRC-16 as implemented for HMS MAC layer packets (see Section 3.3.7). The check code is calculated under any of the following conditions:

1. Upon NE reset (power-up or other reset);
2. An SNMP request for the check code; or
3. At the vendor's discretion.

The NE shall keep track of the last check code it calculated. It shall generate appropriate hmsColdStart and hmsWarmStart SNMP Traps as defined in document SCTE HMS COMMON MIB, *HMS Common Management Information Base*.

The NE shall generate the hmsColdStart SNMP Trap under any of the following conditions:

1. The NE has been reset and the calculated check code differs from the last saved check code; or
2. The check code was calculated at the vendor's discretion and it differs from the last saved check code.

The NE shall generate the hmsWarmStart SNMP Trap under the following conditions:

1. The NE has been reset and the calculated check code is the same as the last saved check code.

The hmsColdStart and hmsWarmStart Traps will *not* be generated by a simple SNMP Get of the check code. Once the appropriate SNMP trap has been generated, the newly calculated check code shall be stored in non-volatile memory.

Appendix B. Glossary

Data Link Layer (DLL)

Layer 2 in the Open System Interconnection (OSI) architecture; the layer that provides services to transfer data over the physical transmission link between open systems.

Forward Spectrum

This term refers to the passband of frequencies in HFC cable systems with a lower edge of between 48 MHz and 87.5 MHz, depending on the particular geographical area, and an upper edge that is typically in the range of 300 MHz to 860 MHz depending on implementation.

Full Spectrum

This term refers to the combined forward and return spectrums in HFC cable systems and excludes any guard band.

Guard Band

This term refers to the unused frequency band between the upper edge of the usable return spectrum and the lower edge of the usable forward spectrum in HFC cable systems.

Network Element (NE)

In the context of this specification, a network element is an active element in the outside plant (OSP) that is capable of receiving commands from a headend element (HE) in the headend and, as necessary, providing status information and alarms back to the HE.

Open System Interconnection (OSI)

A framework of International Organization for Standardization (ISO) standards for communication between multi-vendor systems that organizes the communication process into seven different categories that are placed in a layered sequence based on the relationship to the user. Each layer uses the layer immediately below it and provides services to the layer above. Layers 7 through 4 deal with end-to-end communication between the message source and destination, and layers 3 through 1 deal with network functions.

Organizationally Unique Identifier (OUI)

A 3-octet IEEE assigned identifier that can be used to generate Universal LAN MAC addresses and Protocol Identifiers per ANSI/IEEE Std 802 for use in Local and Metropolitan Area Network applications.

Physical (PHY) Layer

Layer 1 in the Open System Interconnection (OSI) architecture; the layer that provides services to transmit bits or groups of bits over a transmission link between open systems and which entails electrical, mechanical and handshaking procedures.

Return Spectrum

This refers to the passband of frequencies in HFC cable systems with a lower edge of 5 MHz and an upper edge that is typically in the range of 42 MHz to 65 MHz depending on the particular geographical area.

Transponder

A device that interfaces to outside plant (OSP) NEs and relays status and alarm information to the HE. It can interface with an active NE via an arrangement of parallel analog, parallel digital and serial ports.

Appendix C. List of Acronyms

CRC.....	Cyclic Redundancy Code
DLL.....	Data Link Layer
EMS	Element Management System
FCS	Frame Check Sequence
HE	Headend Element
HFC.....	Hybrid Fiber Coax
HMS	Hybrid Management Sub-Layer
IEEE	Institute of Electrical and Electronics Engineers
IP.....	Internet Protocol
ISO	International Organization for Standardization
LSB	Least Significant Bit
MSB	Most Significant Bit
NE	Network Element
MAC	Media Access Control
OSP	Outside Plant
OSI	Open System Interconnection
OUI	Organizationally Unique Identifier
PDU.....	Protocol Data Unit
PHY.....	Physical
POSIX.....	Portable Operating System Interface
RF.....	Radio Frequency
SCTE.....	Society of Cable Telecommunications Engineers
SNMP.....	Simple Network Management Protocol
UART.....	Universal Asynchronous Receiver/Transmitter
